(54) Title: SENESCENT CELL-DERIVED INHIBITORS OF DNA SYNTHESIS**(57) Abstract**

An expression vector cDNA library derived from senescent cells has been used to isolate cDNA clones that encode inhibitors of DNA synthesis. Such inhibitors play a role in cellular senescence, aging and neoplasia. Antisense nucleic acids reduce the inhibition of DNA synthesis. The invention concerns such molecules, their inhibitors, antagonists and derivatives. The invention also concerns diagnostic, therapeutic and in vitro uses for all such agents.

TITLE OF THE INVENTION:

**SENESCENT CELL-DERIVED INHIBITORS OF DNA
SYNTHESIS**

5
FIELD OF THE INVENTION:

10 The present invention is in the field of recombinant DNA technology. This invention is directed to a gene sequence and a protein that effects the ability of cells to become senescent. This invention was supported with Government funds. The Government has certain rights in this invention.

CROSS-REFERENCE TO RELATED APPLICATIONS:

15 This Application is a continuation-in-part of U.S. Patent Appln. Serial No. 08/274,535 (filed July 13, 1994), which is a continuation-in-part of U.S. Patent Appln. Serial No. 08/229,420 (filed April 15, 1994), which is a continuation-in-part of
20 U.S. Patent Appln. Serial No. 08/203,535 (filed February 25, 1994), which is a continuation-in-part of U.S. Patent Appln. Serial No. 08/153,564 (filed November 17, 1993) which is a continuation-in-part of U.S. Patent Appln. Serial No. 08/113,372 (filed August 30, 1993) which is a continuation-

30 continuations-in-part of U.S. Patent Appln. Serial No. 07/808,523 (filed December 16, 1991, now abandoned).

BACKGROUND OF THE INVENTION:

35 Normal human diploid cells have a finite potential for proliferative growth (Hayflick, L. *et al.*, *Exp. Cell Res.* 25:585 (1961); Hayflick, L., *Exp. Cell Res.* 37:614 (1965)). Indeed, under controlled conditions *in vitro* cultured human cells can

maximally proliferate only to about 80 cumulative population doublings. The proliferative potential of such cells has been found to be a function of the number of cumulative population doublings which the cell has undergone (Hayflick, L. *et al.*, *Exp. Cell Res.* 25: 585 (1961); Hayflick, L. *et al.*, *Exp. Cell Res.* 37: 614 (1985)). This potential is also inversely proportional to the *in vivo* age of the cell donor (Martin, G.M. *et al.*, *Lab. Invest.* 23:86 (1979); Goldstein, S. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 64:155 (1969); Schneider, E.L., *Proc. Natl. Acad. Sci. (U.S.A.)* 73:3584 (1976); LeGuilty, Y. *et al.*, *Gereontologia* 19:303 (1973)).

Cells that have exhausted their potential for proliferative growth are said to have undergone "senescence." Cellular senescence *in vitro* is exhibited by morphological changes and is accompanied by the failure of a cell to respond to exogenous growth factors. Cellular senescence, thus, represents a loss of the proliferative potential of the cell. Although a variety of theories have been proposed to explain the phenomenon of cellular senescence *in vitro*, experimental evidence suggests that the age-dependent loss of proliferative potential may be the function of a genetic program (Orgel, L.E., *Proc. Natl. Acad. Sci. (U.S.A.)* 49:517 (1963); De Mars, R. *et al.*, *Human Genet.* 16:87 (1972); M. Buchwald, *Mutat. Res.* 44:401 (1977); Martin, G.M. *et al.*, *Amer. J. Pathol.* 74:137 (1974); Smith, J.R. *et al.*, *Mech. Age. Dev.* 13:387 (1980); Kirkwood, T.B.L. *et al.*, *Theor. Biol.* 53:481 (1975).

Cell fusion studies with human fibroblasts *in vitro* have demonstrated that the quiescent phenotype of cellular senescence is dominant over the proliferative phenotype (Pereira-Smith, O.M. *et al.*, *Somat. Cell Genet.* 8:731 (1982); Norwood, T.H. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 71:223 (1974); Stein, G.H. *et al.*, *Exp. Cell Res.* 130:155 (1979)).

Insight into the phenomenon of senescence has been gained from studies in which senescent and young (i.e. non-senescent) cells have been fused to form heterodikaryons. In order to induce senescence in the "young" nucleus of the heterodikaryon (as determined by an inhibition in the synthesis of DNA), protein synthesis must occur in the senescent cell

3

prior to fusion (Burner, G.C. *et al.*, *J. Cell. Biol.* 94:187 (1982); Drescher-Lincoln, C.K. *et al.*, *Exp. Cell Res.* 144:455 (1983); Burner, G.C. *et al.*, *Exp. Cell Res.* 145:708 (1983); Drescher-Lincoln, C.K. *et al.*, *Exp. Cell Res.* 153:208 (1984).

5 Likewise, microinjection of senescent fibroblast mRNA into young fibroblasts has been found to inhibit the ability of the young cells to synthesize DNA (Lumpkin, C.K. *et al.*, *Science* 232:393 (1986)). Researchers have identified unique mRNAs that are amplified in senescent cells *in vitro* (West, M.D. *et al.*,
10 *Exp. Cell Res.* 184:138 (1989); Giordano, T. *et al.*, *Exp. Cell Res.* 185:399 (1989)).

 The human diploid endothelial cell presents an alternative cell type for the study of cellular senescence because such cells mimic cellular senescence *in vitro* (Maciag, T. *et al.*, *J.*
15 *Cell. Biol.* 91:420 (1981); Gordon, P.B. *et al.*, *In Vitro* 19:661 (1983); Johnson, A. *et al.*, *Mech Age. Dev.* 18:1 (1982); Thornton, S.C. *et al.*, *Science* 222:623 (1983); Van Hinsbergh, V.W.M. *et al.*, *Eur. J. Cell Biol.* 42:101 (1986); Nichols, W.W. *et al.*, *J. Cell. Physiol.* 132:453 (1987)).

20 In addition, the human endothelial cell is capable of expressing a variety of functional and reversible phenotypes. The endothelial cell exhibits several quiescent and non-terminal differentiation phenotypes (Folkman, J. *et al.*, *Nature* 288:551 (1980); Maciag, T. *et al.*, *J. Cell Biol.* 94:511 (1982);
25 Madri, J.A. *et al.*, *J. Cell Biol.* 97:153 (1983); Montesano, R., *J. Cell Biol.* 99:1706 (1984); Montesano, R. *et al.*, *J. Cell Physiol.* 34:460 (1988)).

 It has been suggested that the pathway of human cell differentiation *in vitro* involves the induction of cellular
30 quiescence mediated by cytokines that inhibit growth factor-induced endothelial cell proliferation *in vitro* (Jay, M. *et al.*, *Science* 228:882 (1985); Madri, J.A. *et al.*, *In Vitro* 23:387 (1987); Kubota, Y. *et al.*, *J. Cell Biol.* 107:1589 (1988); Ingber, D.E. *et al.*, *J. Cell Biol.* 107:317 (1989)).

35 Inhibitors of endothelial cell proliferation also function as regulators of immediate-early transcriptional events induced during the endothelial cell differentiation *in vitro*, which involves formation of the capillary-like, tubular

- endothelial cell phenotype (Maciag, T., In: *Imp. Adv. Oncol.* (De Vita, V.T. *et al.*, eds., J.B. Lippincott. Philadelphia, 42 (1990); Goldgaber, D. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 86:7606 (1990); Hla, T. *et al.*, *Biochem. Biophys. Res. Commun.* 167:637 (1990)). The inhibitors of cell proliferation include:
1. Interleukin-1a (IL-1a) (Montesano, R. *et al.*, *J. Cell Biol.* 99:1706 (1984); Montesano, R. *et al.*, *J. Cell Physiol.* 122:424 (1985); Maciag, T. *et al.* (*Science* 249:1570-1574 (1990));
 - 10 2. Tumor necrosis factor (Frater-Schroder, M. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 84:5277 (1987); Sato, N. *et al.*, *J. Natl. Cancer Inst.* 76:1113 (1986); Pber, J.P., *Amer. J. Pathol.* 133:426 (1988); Shimada, Y. *et al.*, *J. Cell Physiol.* 142:31 (1990));
 - 15 3. Transforming growth factor- β (Baird, A. *et al.*, *Biochem. Biophys. Res. Commun.* 138:476 (1986); Mullew, G. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 84:5600 (1987); Mairi, J.A. *et al.*, *J. Cell Biol.* 106:1375 (1988));
 4. Gamma-interferon (Friesel, R. *et al.*, *J. Cell Biol.* 104:689 (1987); Tsuruoka, N. *et al.*, *Biochem. Biophys. Res. Commun.* 155:429 (1988)) and
 - 20 5. The tumor promoter, phorbol myristic acid (PMA) (Montesano, R. *et al.*, *Cell* 42:469 (1985); Doctrow, S.R. *et al.*, *J. Cell Biol.* 104:679 (1987); Montesano, R. *et al.*, *J. Cell Physiol.* 130:284 (1987); Hoshi, H. *et al.*, *FASAB J.* 2:2797 (1988)).
 - 25

The prospect of reversing senescence and restoring the proliferative potential of cells has implications in many fields of endeavor. Many of the diseases of old age are associated with the loss of this potential. Restoration of this ability would have far-reaching implications for the treatment of this disease, of other age-related disorders, and, of aging per se.

30

In addition, the restoration of proliferative potential of cultured cells has uses in medicine and in the pharmaceutical industry. The ability to immortalize nontransformed cells can be used to generate an endless supply of certain tissues and also of cellular products.

35

The significance of cellular senescence has accordingly been appreciated for several years (Smith, J.R., *Cellular Ageing*,

In: *Monographs in Developmental Biology*, Sauer, H. W. (Ed.), S. Karger, New York, N.Y. 17:193-208 (1984); Smith, J.R. *et al.*, *Exper. Gerontol.* 24:377-381 (1989), herein incorporated by reference). Researchers have attempted to clone genes relevant to cellular senescence. A correlation between the existence of an inhibitor of DNA synthesis and the phenomenon of cellular senescence has been recognized (Spiering, A.I. *et al.*, *Exper. Cell Res.* 179:159-167 (1988); Pereira-Smith, O.M. *et al.*, *Exper. Cell Res.* 160:297-306 (1985); Drescher-Lincoln, C.K. *et al.*, *Exper. Cell Res.* 153:208-217 (1984); Drescher-Lincoln, C.K. *et al.*, *Exper. Cell Res.* 144:455-462 (1983)). Moreover, the relative abundance of certain senescence-associated RNA molecules has been identified (Lumpkin, C.K. *et al.*, *Science* 232:393-395 (1986)).

Several laboratories have used the "subtraction-differential" screening method to identify cDNA molecules derived from RNA species that are preferentially present in senescent cells (Kleinsek, D.A., *Age* 12:55-60 (1989); Giordano, T. *et al.*, *Exper. Cell. Res.* 185:399-406 (1989); Sierra, F. *et al.*, *Molec. Cell. Biol.* 9:5610-5616 (1989); Pereira-Smith, O.M. *et al.*, *J Cell. Biochem. (Suppl 0 (12 part A))* 193 (1988); Kleinsek, D.A., Smith, J.R., *Age* 10:125 (1987)).

In one method, termed "subtraction-differential" screening, a pool of cDNA molecules is created from senescent cells, and then hybridized to cDNA or RNA of growing cells in order to "subtract out" those cDNA molecules that are complementary to nucleic acid molecules present in growing cells. Although useful, for certain purposes, the "subtraction-differential" method suffers from the fact that it is not possible to determine whether a senescence-associated cDNA molecule is associated with the cause of senescence, or is produced as a result of senescence. Indeed, many of the sequences identified in this manner have been found to encode proteins of the extra-cellular matrix. Changes in the expression of such proteins would be unlikely to cause senescence.

SUMMARY OF THE INVENTION:

The present invention concerns, in part, the observation that normal human cells exhibit a limited replicative potential in vitro and become senescent after a certain number of divisions. As the cells become senescent, they show several morphological and biochemical changes, such as enlargement of cell size, changes of extracellular matrix components, unresponsiveness to mitogen stimulation and failure to express growth regulated genes.

The present invention identifies an inhibitor of DNA synthesis that is produced in senescent cells. This inhibitor plays a crucial role in the expression of the senescent phenotype. The gene coding for the inhibitor was identified by incorporating a senescent cell cDNA library into a mammalian expression vector. The cDNA library was then transfected into young, cycling cells to identify those library members that suppressed the initiation of DNA synthesis.

Efficient DEAE dextran-mediated transfection enabled the isolation of putative senescent cell derived inhibitor (SDI) sequences in three distinct cDNA clones. The expression of one (SDI-1) increased 20 fold at cellular senescence, whereas that of the others (SDI-2 and SDI-3) remained constant.

In summary, the present invention achieves the cloning of an inhibitor of DNA synthesis using a functional assay. This method may be applied to clone other genes involved in negative regulation of the cell cycle, such as tissue specific differentiation and tumor suppression genes. Using this method, three inhibitor sequences have been cloned. One of these sequences (SDI-1) appears to be closely related to cellular senescence.

In detail, the invention provides a nucleic acid molecule that encodes a protein or polypeptide capable of inhibiting DNA synthesis in a recipient cell.

In particular, the invention concerns the embodiment wherein such protein or polypeptide is capable of associating with a cyclin or a cyclin-dependent kinase, and especially wherein said cyclin is cyclin D1, and said cyclin-dependent

kinase is CDK2, especially wherein the expression of said protein or polypeptide is regulated by a tumor suppressor gene.

The invention includes such nucleic acid molecules that encode SDI-1, or an SDI-1 fusion protein, a fragment of SDI-1, or an analog of SDI-1, as well as nucleic acid molecules that are capable of hybridizing to SEQ ID NO:1 or the complement of SEQ ID NO:1.

The invention also concerns an oligonucleotide capable of inhibiting the expression of SDI-1 by formation of a triplex structure, wherein the oligonucleotide consists of only G and C residues, and is at least 20 nucleotides in length, and has a nucleotide sequence that can hybridize with a double-stranded nucleic acid molecule that encodes SDI-1, the hybridization being to a region of the double-stranded molecule that is at least about 65% purine or at least about 65% pyrimidine, wherein the oligonucleotide has a G residue when a complementary location in the SDI-1-encoding nucleic acid molecule is a GC base pair and a T residue when a complementary location in the SDI-1-encoding nucleic acid molecule is an AT base pair.

The invention also concerns an antagonist of a protein or polypeptide capable of:

- (i) inhibiting DNA synthesis in a recipient cell and
- (ii) associating with a cyclin or a cyclin-dependent kinase.

The invention particularly concerns antagonists that are nucleic acid molecules or proteins.

The invention also concerns a protein or polypeptide capable of:

- (i) inhibiting DNA synthesis in a recipient cell and
- (ii) associating with a cyclin or a cyclin-dependent kinase.

The invention particularly concerns SDI-1, and fusion proteins and fragments thereof, as well as other molecules having similar attributes, especially if the expression of the molecule is induced by the product of a tumor suppressor gene.

The invention also concerns analog of such molecules that are capable of inhibiting DNA synthesis in a recipient cell and associating with a cyclin or a cyclin-dependent kinase.

5 The invention also includes antibodies, either polyclonal or monoclonal, that bind to SDI-1.

The invention also includes a method for inhibiting the proliferation of a cell, comprising introducing into the cell a drug which (i) inhibits DNA synthesis in a recipient cell and (ii) associates with a cyclin or a cyclin-dependent kinase.

10 The invention also includes a method of determining the presence or concentration of SDI1 in a sample which comprises contacting the sample with an antibody capable of binding SDI-1, and determining the presence or amount of any SDI-1 protein bound to the antibody.

15 The invention also provides a method for inhibiting DNA synthesis in a human cell which comprises providing to the cell an effective amount of the above-stated nucleic acid molecule that encodes a protein capable of inhibiting DNA synthesis in a recipient cell (and especially wherein the cell is a tumor cell, or a cell in in vitro culture.

20 The invention also provides the embodiment of the above method wherein the provided nucleic acid molecule is expressed in the cell, and wherein the expression produces a protein capable of impairing the activity of a cyclin or a cyclin-dependent kinase, especially cyclin D1, and cyclin-dependent kinase CDK2.

25 The invention further concerns the embodiments of the above methods wherein the nucleic acid molecule or its complement is capable of hybridizing to a nucleic acid sequence shown in Figures 5A-5D (SEQ ID NO:1) and/or wherein the nucleic acid molecule encodes a protein analog of a protein encoded by a nucleic acid sequence shown in Figures 5A-5D (SEQ ID NO:1), wherein the analog is capable of impairing the activity of a cyclin or a cyclin-dependent kinase, especially cyclin D1, and cyclin-dependent kinase CDK2.

35 The invention also provides a method for repressing an inhibition of DNA synthesis in a quiescent or senescent human cell which comprises providing to the cell an effective amount

of an SDI inhibitor (protein, nucleic acid or organic). Such nucleic acid molecule (either DNA or RNA) inhibitors may have a sequence complementary to an RNA molecule that encodes a protein capable of inhibiting DNA synthesis in a recipient cell, and having a length sufficient to permit the molecules to hybridize to one another under physiological conditions. Especially contemplated is the embodiment wherein the cell is an endothelial cell, a skin cell or a cell present in wound or burn tissue. The invention further contemplates the use of the agents of the present invention in tissue other than skin, such as lymphocytes, vascular tissue (such as arteries, arterioles, capillaries, veins, etc.), liver, kidney, heart and other muscle, bone, spleen, etc. The invention also concerns the use of SDI molecules to accomplish angiogenesis.

The invention also provides a method for directing the delivery of a pharmacological agent into a target cell which comprises:

(A) conjugating the pharmacological agent to an SDI moiety, the moiety selected from the group consisting of SDI-1 and a fragment of SDI-1 capable of being transported into the target cell; and

(B) incubating the conjugated molecule in the presence of the target cell under conditions sufficient to permit the SDI moiety to be transported into the target cell; the transport accomplishing the delivery of the agent into the target cell.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 shows the structure of the cDNA cloning and expression vector, pcDSR $\alpha\Delta$ (B represents BamHI site).

Figures 2A, 2B and 2C identify cDNA clones inhibitory to young cell DNA synthesis. The different bars represent independent transfection experiments for individual plasmids, * indicates not done, a negative number indicates labeling indices higher than the controls. Each graph shows results from a different pool of plasmids.

Figure 3 shows antisense SDI cDNA transfection. Antisense cDNA expression plasmids were made and co-transfected with pCMV β into young cells. Lane 1: control

pcDSR $\alpha\Delta$, lane 2: pcDSR $\alpha\Delta$ -SDI-1, lane 3: pcDSR $\alpha\Delta$ antiSDI-1, lane 4: pcDSR $\alpha\Delta$ -SDI-2, lane 5: pcDSR $\alpha\Delta$ - antiSDI-2.

Figure 4 shows the changes in poly A+ RNA recovery from total RNA during cellular aging.

5 Figures 5A-5D provide the nucleotide and amino acid sequences of SDI-1 cDNA.

Figure 6 shows the kinetics of SDI-1 induction in young cells (population doubling 28) obtained following exposure to either 4 Gy of γ -irradiation (open circles) or 400 μ M hydrogen
10 peroxide for 1 hour (closed circles).

DETAILED DESCRIPTION OF THE INVENTION:

I. Cellular Senescence

Replicative senescence of normal human diploid fibroblasts in culture is a well established and widely accepted
15 model for cellular aging (Hayflick, L., *Exp. Cell Res.* 37:611-636 (1965); Norwood, T.H., and Smith, J.R., In: *Handbook of the Biology of Aging* (2nd ed.) C.E. Finch and E.L. Schneider, eds. Van Nostrand, New York pp. 291-311 (1985); Goldstein, S., *Science* 249:1129-1133 (1990)). After a limited number of population
20 doublings, as cells become senescent, they lose the capability to divide and display a large and flattened morphology. The causative mechanisms underlying this phenomenon are not yet understood, despite the many observations that characterize senescent cells at the biochemical and molecular levels.

25 One- and two-dimensional protein gel analyses have revealed that there are few senescent cell-specific marker proteins (Lincoln, D.W. *et al.*, *Exp. Cell Res.* 154:136-146 (1984); Wang, E., *J. Cell Biol.* 100:545-551 (1985); Scottie, J. *et al.*, *J. Cell Physiol.* 131:210-217 (1987); Bayreuther, K. *et al.*,
30 *Proc. Natl. Acad. Sci. USA.* 85:5112-5116 (1988)). Antigenic determinants that specify senescent cells have been found on the plasma membrane (Porter, M.B. *et al.*, *J. Cell Physiol.* 142:425-433 (1990)). Components of extracellular matrix, such as fibronectin and collagenase, have been found to be
35 over-expressed in senescent cells (West, M.D. *et al.*, *Exp. Cell Res.* 184:138-147 (1989); Kumazaki, T. *et al.*, *Exp. Cell Res.*

195:13-19 (1991)). However, the relevance of these observations to cellular senescence is not clear.

The cell cycle has been found to be regulated and driven by growth factors. Growth factors act throughout the first gap (G₁) phase of the cell cycle by binding to specific cell surface receptors, which in turn trigger signaling cascades that ultimately govern the transcription of both immediate and delayed early response genes. The growth cycle is controlled by kinases, especially "cyclin-dependent kinases" ("CDKs"), by the "cyclins" themselves, and by phosphatases (Sherr, C.J., *Cell* 73:1059-1065 (1993), herein incorporated by reference).

Considerable effort has been expended to identify the mammalian kinases that are involved in the DNA synthesis cycle. In vertebrate cells, a family of cyclins has been identified (see, Xiong, Y. *et al.*, *Cell* 71:505-514 (1992)). Gene sequences encoding several of these cyclins have been isolated (Motokura, T. *et al.*, *Nature* 350:512-515 (1991); Xiong, Y. *et al.*, *Cell* 65:691-699 (1991); Lew, D.J. *et al.*, *Cell* 65:1197-1206 (1991); Xiong, Y. *et al.*, *Curr. Biol.* 1:362-364 (1991); Matsushime, H. *et al.*, *Cell* 65:701-7139 (1991); Inaba, T. *et al.*, *Genomics* 13:565-574 (1992); Xiong, Y. *et al.*, *Genomics* 13:575-584 (1992)).

The D cyclins interact with CDK2, CDK4 and with CDK5, in order to initiate the growth cycle at the G₁ stage (Matsushime, H. *et al.*, *Cell* 65:701-7139 (1991); Sherr, C.J., *Cell* 73:1059-1065 (1993)). Cyclin E/CDK2 interactions regulate the initiation of S phase (Lew, D.J. *et al.*, *Cell* 66:1197-1206 (1991); Koff, A. *et al.*, *Cell* 66:1217-1228 (1991)). Cyclin A has been suggested to interact with CDK2 to regulate the S phase of the growth cycle (Sherr, C.J., *Cell* 73:1059-1065 (1993)). Cyclins A and B are believed to interact with CDC2 to mediate termination of S phase and initiation of G₂ phase (Norbury, C. *et al.*, *Ann. Rev. Biochem.* 61:441-470 (1992); Fang, F. *et al.*, *Cell* 66:731-742 (1991); Walker, D.H. *et al.*, *Nature* 354:314-317 (1991)).

Recently, changes in the expression of several growth regulated genes have been identified. Expression of c-fos CDC2, cyclins A and B have been found to be impaired in

senescent cells (Seshadri, T. *et al.*, *Science* 247:205-209 (1990)). Similarly, senescent cells evidence an inability to phosphorylate the retinoblastoma protein (Stein, G.H. *et al.*, *Science* 249:666-669 (1990)). These observations could potentially explain the inability of the cells to enter S phase, since they are all deteriorative changes of growth promoting gene expression, however, it is not clear whether they are the cause or result of senescence.

One additional change in gene expression that could have a causal role in senescence is the inhibitor(s) of DNA synthesis produced by senescent but not young fibroblasts (see, Spiering, A.I. *et al.*, *Exper. Cell Res.* 195:541-545 (1991)). Evidence for the existence of the inhibitor(s) was first obtained from heterokaryon experiments in which senescent cells inhibited initiation of DNA synthesis in young nuclei within the heterokaryon (Norwood, T.H., *et al.*, *Proc. Natl. Acad. Sci. USA.* 71:2231-2234 (1974); Pereira-Smith, O.M., and Smith, J.R., *Somat. Cell Genet.* 8:731-742 (1982)). Studies with cybrids involving senescent cytoplasts and whole young cells lent further support for the presence of a surface membrane associated protein inhibitor of DNA synthesis in senescent cells (Drescher-Lincoln, C.K., and Smith, J.R., *Exp. Cell Res.* 153:208-217 (1984)). This was directly demonstrated when surface membrane enriched preparations from senescent cells or proteins extracted from the membranes were found to inhibit DNA synthesis when added to the culture medium of young cells (Pereira-Smith, O.M. *et al.*, *Exp. Cell Res.* 160:297-306 (1985); Stein, G.H., and Atkins, L., *Proc. Natl. Acad. Sci. USA.* 83:9030-9034 (1986)). Purification of that inhibitor by biochemical methods has been unsuccessful to date. However, in microinjection experiments, the presence of a high abundance of DNA synthesis inhibitory messenger RNA has been demonstrated (Lumpkin, C.K. *et al.*, *Science* 232:393-395 (1986)).

In order to attempt to clone the gene(s) coding for the DNA synthesis inhibitor(s), a functional screening procedure was employed. This method led to the isolation and identification of three cDNA species that exhibit DNA synthesis

inhibitory activity when introduced into young cycling cells. These molecules are a preferred class of the molecules referred to herein as "senescent cell derived inhibitors" ("SDI").

5 Subsequent to the cloning, isolation, sequencing and characterization of the SDI molecules of the present invention (see, for example PCT Application Publication No. US93/12251), other research groups conducted similar efforts. Such subsequent efforts have described the SDI-1 molecule of
10 the present invention as WAF1, CIP1, PIC1 and p21 (Harper, J.W. *et al.*, *Cell* 75:805-816 (1993); El-Deiry, W.S. *et al.*, *Cell* 75:817-825 (1993); Xiong, Y. *et al.*, *Nature* 366:701-704 (1993); Hunter, T. *et al.*, *Cell* 75:839-841 (1993)).

II. The Cloning of Inducers of Cellular Senescence

15 In the practice of the present invention, an efficient method for the molecular cloning of the DNA synthesis inhibitory sequences present in senescent human diploid fibroblasts is preferably employed. As is often the case when
20 attempting to clone biologically important genes, it may not be possible to purify a desired gene responsible for cellular senescence, even though the activity of its products could be readily detected.

One method that might be envisioned for identifying such a gene sequence would be to employ a differential or
25 subtractive screening of a senescent cell derived cDNA library. This method has been used to identify cDNA molecules that are overexpressed in cells from Werner Syndrome patients (Murano, S. *et al.*, *Molec. Cell. Biol.* 11:3905-3914 (August 1991)). Werner Syndrome is a rare inherited disorder. It is
30 characterized by premature aging. The relevance of Werner Syndrome to natural aging is unknown.

Unfortunately, such screenings would identify a number of genes that, although important for the characterization of senescent cells, would not be primarily responsible for
35 senescence. Furthermore, technical limitations in cloning full-length cDNA make it difficult to determine the function of genes cloned by these methods. For these reasons, such

differential methods are neither generally suitable, or the most desirable method of identifying senescence-related gene sequences.

5 In contrast, expression screening provides a preferred method for identifying and isolating such senescence-related gene sequences. In such a screening method, the cDNA is cloned directly into a vector that is capable of expressing the cloned gene in a recipient cell. The recipient cells can thus be directly screened for any inhibition in DNA synthesis.

10 In expression screening, the most important step is the synthesis of cDNAs. Enzymes should be carefully chosen to be free of impurities. The cDNA synthesis is preferably repeated several times to ensure that satisfactory results (i.e. faithful reverse transcription, and full length transcript size) will be
15 obtained. Finally, the cDNA products are preferably size fractionated to eliminate fragmented and prematurely terminated cDNA products. Double-stranded cDNA products are then preferably divided into fractions based on size, i.e., 0.5-2.0, 2.0-4.5, and 4.5-10 kb fractions. The 2-4.5 kb cDNA
20 fraction was used to make the cDNA library on the assumption that many membrane associated proteins have a relatively high molecular weight. The cDNAs are inserted into a suitable expression vector, preferably pcDSR $\alpha\Delta$, in which the inserted sequences can be transcribed at high levels in young cells.

25 The most preferred transfection procedure is DEAE dextran-mediated transfection, carried out under conditions that allow for transient expression in a high percentage of young cycling cells. Since the transfection frequencies could vary from experiment to experiment, the cDNA pool plasmids
30 were transfected along with a marker plasmid, such as pCMV β (encoding β -galactosidase), and the labeling index was assayed in only β -galactosidase positive cells. Generally, co-expression of transfected genes is quite high, since transfection competent cells will accept multiple plasmids.
35 This simple co-transfection method enabled the evaluation of DNA synthesis in cells expressing exogenous DNA.

The amount of plasmid to be co-transfected can be readily determined from pilot experiments. When the

correlation between the transfection frequency and the amount of plasmid added is examined using a marker plasmid, maximum efficiency is obtained at a range of 100-500 ng of plasmid. Taking into account this result, the cDNA library is preferably
5 divided into small pools in which every pool contained five independent plasmid clones. Then the co-transfection is carried out with approximately 100 ng of pCMV β and approximately 400 ng of cDNA plasmid. These parameters were found to maximize the co-expression of cDNA in
10 β -galactosidase positive cells without decreasing the transfection frequency of the marker plasmid.

After the second round of screening, single plasmids which showed strong inhibition of DNA synthesis can be successfully isolated from the pool that tested positive during
15 the first round screenings (Figures 2A, 2B, 2C). In Figures 2A, 2B and 2C, cDNA pools which showed positive in the first round screenings were divided into individual plasmid, and transfected again. For every cDNA pool (A, B and C in Figures 2A, 2B, 2C, respectively), plasmid No. 1 to 5 represents the
20 result of each single plasmid transfection. In pool B, No. 1 plasmid was found to be only the empty vector. The inhibitory activities of the plasmids are preferably further confirmed by nuclear microinjection experiments. Such experiments provide more direct evidence that the isolated plasmids contain
25 sequences capable of inhibiting DNA synthesis.

III. The Molecules of the Present Invention

The agents of the present invention (collectively referred to as "SDI molecules") are capable of either inducing the
30 inhibition of DNA synthesis in active cells, or suppressing such inhibition in senescent or quiescent cells. As such, they may be used for a wide range of therapies and applications.

The SDI molecules of the present invention include SDI nucleic acid molecules (e.g., SDI-1 encoding nucleic acid
35 molecules, SDI-1 fragment encoding molecules, SDI-1 fusion encoding molecules, SDI antisense molecules, SDI triplex repressor molecules, etc.), SDI protein molecules (i.e. SDI-1, and its fusions and fragments, antibodies to such molecules, and

protein analogs and mimetics of such molecules), and non-protein mimetics and analogs of such molecules.

Such molecules may either naturally occurring or non-naturally occurring. A naturally occurring SDI-1 molecule may be
5 purified, such that one or more molecules that is or may be present in a naturally occurring preparation containing the molecule has been removed or is present at a lower concentration than that at which it would normally be found.

The molecules of the present invention may be either
10 nucleic acids, proteins, carbohydrates, or, more preferably, organic molecules that have a tertiary structure which resembles or mimics the structure of a SDI protein molecule. The present invention further concerns the use of biologically active fragments of molecules, such as SDI nucleic acid
15 molecules, SDI protein molecules, etc. in lieu of or in addition to any naturally occurring SDI molecule. As used herein, a molecule is said to be "biologically active" with respect to cellular proliferation if it is capable of mediating an affect on the proliferative capacity of a recipient cell. Such biological
20 activity may be a structural attribute, such as the capacity to mediate antisense repression, or the ability to bind at a particular nucleic acid site, or with a particular active site of a protein, receptor, etc. (or to compete with another molecule for such binding) Alternatively, such an attribute may be
25 catalytic, and involve the capacity of the biologically active molecule to mediate a chemical reaction or response in a recipient cell.

The present invention permits the isolation of all such SDI molecules in a "purified" form. As used herein, an SDI
30 molecule is said to be "purified" if it is present in a preparation that lacks a molecule that is normally associated with the SDI molecule in its natural state. Proteins, lipids, nucleic acid sequences that do not encode SDI molecules are examples of molecules that are naturally associated with SDI
35 molecules.

A. SDI Nucleic Acid Molecules and Their Oligonucleotide or Polynucleotide Fragments

A preferred class of SDI nucleic acid molecules includes the nucleic acid molecules: SDI-1, SDI-2, and SDI-3, and their
5 biologically active fragments. To identify such fragments, the SDI nucleic acid molecules can be cleaved, as by mechanical methods or more preferably restriction endonuclease cleavage to thereby generate candidate fragments. Such fragments can then be provided to cells, and monitored for their capacity to
10 inhibit DNA synthesis. In one embodiment, gene sequences that encode fragments of protein SDI molecules can be administered to a recipient cell.

By administering fragments of nucleic acid SDI molecules (with or without linked sequences) it is possible to assess
15 whether a particular fragment of an SDI nucleic acid molecule has biological activity due to its structure. Thus, for example, such candidate SDI molecules could be introduced into either a normal, immortalized, or tumor cell, and the capacity of the cell to undergo further proliferation can be monitored. In this
20 manner, sequences that repress cellular proliferation, or induce quiescence can be identified.

Through the use of such methods, nucleic acid molecules that encode the amino terminal half of SDI-1 have been found to exhibit the capacity to convert immortalized cells or tumor
25 cells to a quiescent state. More specifically, nucleic acid molecules that encode SDI-1 amino acid residues 1-70 have been found to be capable of inducing cellular quiescence. The recognition that residues 1-70 contain a catalytic domain of SDI-1 indicates that other fragments of the SDI-1 encoding
30 sequence have catalytic activity. Preferred candidate oligonucleotide fragments include nucleic acid molecules that encode SDI-1 amino acid residues: 5-70, 10-70, 15-70, 20-70, 25-70, 30-70, 35-70 or 40-70.

As discussed below, one aspect of the present invention
35 concerns methods for determining the level of SDI-1 mRNA. Nucleic acid molecules that are capable of hybridizing to an SDI nucleic acid molecules can be used for such diagnostic purposes. As used herein, two nucleic acid molecules are said

to be capable of hybridizing to one another if the two molecules are capable of forming an anti-parallel, double-stranded nucleic acid structure. The molecules are said to be "minimally complementary" if they can hybridize to one another with sufficient stability to permit them to remain annealed to one another under at least conventional "low-stringency" conditions. Similarly, the molecules are said to be "complementary" if they can hybridize to one another with sufficient stability to permit them to remain annealed to one another under conventional "high-stringency" conditions. As will be appreciated, complementary molecules need not exhibit "complete complementarity" (i.e. wherein every nucleotide of one of the molecules is complementary to a nucleotide of the other), but need only be sufficiently complementary in sequence to be able to form a stable double-stranded structure under defined solvent and salt concentrations. A nucleic acid molecule is said to be the "complement" of another nucleic acid molecule if they exhibit complete complementarity. Conventional stringency conditions are described by Sambrook, J., et al., (In: *Molecular Cloning, a Laboratory Manual, 2nd Edition*, Cold Spring Harbor Press, Cold Spring Harbor, New York (1989)), and by Haymes, B.D., et al. (In: *Nucleic Acid Hybridization, A Practical Approach*, IRL Press, Washington, DC (1985)), both herein incorporated by reference). Departures from complete complementarity are therefore permissible, as long as such departures do not completely preclude the capacity of the molecules to form a double-stranded structure.

The nucleic acid molecules that can be used to hybridize to an SDI nucleic acid molecule will preferably be shorter than such SDI molecule. Preferred molecules will be completely complementary to an SDI nucleic acid molecule, and will have a length of between about 15 to about 250 nucleotides, and most preferably about 15 to about 30 nucleotides.

Such nucleic acid molecules may be obtained using solid phase oligonucleotide synthetic methods, however, more preferably, such molecules will be obtained via the polymerase-mediated, template-dependent extension of a primer molecule that is complementary to a fragment of an SDI

nucleic acid molecule. Such fragments of SDI nucleic acid molecules will have a length of between about 15 to about 250 nucleotides, and most preferably about 15 to about 30 nucleotides. Such fragments may be DNA or RNA, and may be
5 incorporated into vectors, or be substantially free of other nucleic acid molecules.

B. The Proteins and Polypeptides Encoded by Nucleic Acid SDI Molecules

10 The present invention further includes the proteins and polypeptides encoded by the SDI nucleic acid molecules or their oligonucleotide fragments. The sequences of SDI nucleic acid molecules permits one to ascribe and identify encoded protein and polypeptide molecules that can be used either to suppress
15 the inhibition of DNA synthesis associated with quiescence and senescence, or to induce such states in proliferating cells. The amino acid sequence of such molecules can be readily derived from the known relationship between the nucleotide sequence of a nucleic acid molecule, and the amino acid sequence of the
20 protein it encodes. Therapeutically active proteins and polypeptides can be identified using a method that is analogous to the above-described method for identifying therapeutically active SDI nucleic acid fragments. By mutating such proteins, it is possible to identify molecules that have lost the capacity
25 to inhibit DNA synthesis. Among such mutated molecules will be proteins that are capable of exerting a dominant effect sufficient to reverse the inhibitory effect of SDI-encoded proteins and polypeptides.

In one embodiment, such molecules are identified by
30 cleaving nucleic acid SDI molecules, and then incorporating the cleavage fragments into translatable expression vectors. In this manner, a library of nucleic acid molecules, each producing a different peptide fragment can be obtained and evaluated. Such expression may be free of additional or extraneous
35 protein, or may comprise a fusion of an SDI fragment to a particular fusion protein. The biological activity of the expressed proteins can be assessed either by introducing such fragments into recipient cells, and determining the affect of

such introduction on quiescence or proliferation. Alternatively, such molecules can be passed through columns that have been pretreated to bind biologically active SDI molecules. Such columns may, for example, contain bound p53, SDI-1, RB, cyclin D, cdk2, etc., in order to identify fragments that have the capacity to bind to such molecules.

Examples of protein fragment SDI molecules include the first 70 amino acids of SDI-1, which has a biological activity similar to that of SDI-1. Smaller fragments (such as those containing SDI-1 residues: 5-70, 10-70, 15-70, 20-70, 25-70, 30-70, 35-70 or 40-70) may also be employed. Protein fragments that possess SDI-1 amino acid residues 29-45 are particularly desirable. When conserved amino acid substitutions are considered, this region of SDI-1 exhibits 31% identity and 62% similarity to PCNA. Since SDI-1 and PCNA both interact with cyclin-Cdk complexes, the conserved region in common (SDI-1 amino acid residues 29-45) are believed to be involved in such interactions. Hence, fragments of SDI-1 that contain this conserved region comprise inhibitors of SDI-1, and may indeed exhibit SDI-1 function.

Typically, the SDI proteins and protein fragments will be produced free of any additional amino acid residues. Alternatively, the SDI proteins and protein fragments may be produced fused to an amino acid or to a polypeptide. Such synthesis may be accomplished using conventional peptide synthetic means, or, more preferably, using recombinant methods. Where fusion molecules are desired, such molecules may contain selectable cleavage sites such that the SDI portion of the fusion molecule may be cleaved from the remaining portion(s) of the fusion protein.

A particularly preferred fusion molecule results from fusing a glutathione S-transferase glutathione binding sequence to the amino terminus of the SDI molecule. Such fusion proteins can be readily recovered by their retention to a column. The fusion protein can be removed from the column by washing with glutathione. An GST-SDI-1 fusion protein can be produced by peptide synthesis, such as by synthesizing the SDI protein as a fusion with glutathione S-transferase.

Alternatively, recombinant DNA methods can be used to join a GST-encoding polynucleotide to a polynucleotide that encodes SDI-1 or a fragment thereof. The sequence of glutathione S-transferase (GST) is known, and vectors that contain this sequence have been described (see, Ross, V.L., *et al.*, *Biochem. J.* 294:373-380 (1993); Comstock, K.E. *et al.*, *J. Biol. Chem.* 268:16958-16965 (1993); Takahasi, Y. *et al.*, *J. Biol. Chem.* 268:8893-8898 (1993); Klone, A. *et al.*, *Biochem. J.* 285:925-928 (1992); Sternberg, G. *et al.*, *Protein Express. Purif.* 3:80-84 (1992); Morrow, C.S. *et al.*, *Gene* 75:3-12 (1989)).

An alternative preferred fusion molecule has an amino terminal [His]₆ leader sequence. The presence of such leader sequences does not substantially reduce the activity of the SDI proteins. More preferably, a leader sequence having the sequence MRGSHHHHHHGA [SEQ ID NO:4] coupled to the amino terminal methionine of SDI-1 will be employed.

A preferred fusion includes essentially all of the GST protein. An especially preferred fusion employs the GST of *Schistosoma japonicum*. The sequence of this GST is described by Smith *et al* (*Gene* 67:31 (1988)), and the polynucleotide that encodes this GST can be obtained commercially (pGEX-2T; Pharmacia). The DNA sequence encoding the GST of *Schistosoma japonicum* is shown as SEQ ID NO:5; the encoded amino acid sequence is shown in SEQ ID NO:6. Any of a variety of methods may be used to create such a preferred fusion; a detailed method is provided in Example 20. In one embodiment, a restriction endonuclease recognition site in the *Schistosoma japonicum* GST-encoding polynucleotide can be used to cleave that polynucleotide. The cleavage product can then be ligated to a polynucleotide that encodes a desired SDI molecule. Thus, for example, a preferred fusion can be made by cleaving the GST-encoding sequence of *Schistosoma japonicum* with BamHI so as to obtain a polynucleotide fragment that contains nucleotides 1-673 of the GST-encoding polynucleotide (the BamHI cleaving at a site located at nucleotides 673-678 of the molecule) and then ligating that fragment to an SDI gene sequence (such as a polynucleotide that encodes SDI-1). Where, for example, a polynucleotide that encodes SDI-1 is employed,

the gene fusion would link the GST fragment to the SDI-1 polynucleotide such that, upon expression, a fusion protein containing the first 226 of the 232 amino acids of GST linked to the amino terminus of SDI-1 would be produced.

- 5 As discussed below, one aspect of the present invention concerns antibodies to SDI-1. The above-described proteins and polypeptides can be used to elicit polyclonal or monoclonal antibodies that can be used in accordance with the methods of the present invention.

10 **C. Functional Analogs of the SDI Molecules**

- The present invention also pertains to "functional analogs" of the SDI molecules. Such analogs include both "classical analogs" and "mimetic analogs." A classical analog of an SDI molecule is one that has a similar biological activity, and is chemically related to the SDI molecule. By way of illustration, a non-naturally occurring mutant protein having SDI activity would comprise a classical analog of a protein SDI molecule. Similarly, a mutated SDI nucleic acid molecule would comprise an example of a classical analog of an SDI gene sequence. Likewise, an SDI molecule isolated from a non-human mammalian species (such as a mouse, monkey, etc.) would comprise an example of a classical analog of an SDI gene sequence. In contrast, a "mimetic analog" of an SDI molecule retains the biological activity of the molecule, but will typically be unrelated chemically. An organic molecule whose structure mimics the active site of an SDI protein would comprise a "mimetic analog" of that protein. Similarly, non-nucleic acid molecules capable of binding to a nucleic acid binding site of SDI, or recognized by SDI would be a mimetic analog of that molecule.

- Thus, functional analogs may be either an oligonucleotide or polynucleotide, a proteinaceous compound (including both glycosylated and non-glycosylated proteins), or a non-proteinaceous compound (such as a steroid, a glycolipid, etc.) provided that the agent mimics the function of either an entire SDI nucleic acid molecule, or an oligonucleotide or polynucleotide fragment thereof, or a protein or polypeptide

encoded by such a molecule or fragment. Preferred classical analogs include polypeptides (including circular as well as linear peptides) whose sequences comprise the active catalytic or binding sites of an SDI protein, or oligonucleotide fragments of nucleic acid SDI molecules that are capable of either repressing or inducing SDI activity. Preferred mimetic analogs include polypeptides that are not fragments of an SDI protein, or mutants thereof, but nevertheless exhibit a capacity to induce quiescence in an SDI-like manner, or to induce cellular proliferation in the manner of an SDI antagonist.

Classical analogs can be identified either rationally, as described below, or via established methods of mutagenesis (see, for example, Watson, J.D. *et al.*, *Molecular Biology of the Gene*, Fourth Edition, Benjamin/Cummings, Menlo Park, CA (1987). Significantly, a random mutagenesis approach requires no *a priori* information about the gene sequence that is to be mutated. This approach has the advantage that it assesses the desirability of a particular mutant on the basis of its function, and thus does not require an understanding of how or why the resultant mutant protein has adopted a particular conformation. Indeed, the random mutation of target gene sequences has been one approach used to obtain mutant proteins having desired characteristics (Leatherbarrow, R.J. *Prot. Eng.* 1:7-16 (1986); Knowles, J.R., *Science* 236:1252-1258 (1987); Shaw, W.V., *Biochem. J.* 246:1-17 (1987); Gerit, J.A. *Chem. Rev.* 87:1079-1105 (1987)). Alternatively, where a particular sequence alteration is desired, methods of site-directed mutagenesis can be employed. Thus, such methods may be used to selectively alter only those amino acids of the protein that are believed to be important (Craik, C.S., *Science* 228:291-297 (1985); Cronin, C.S. *et al.*, *Biochem.* 27:4572-4579 (1988); Wilks, H.M. *et al.*, *Science* 242:1541-1544 (1988)).

Nucleic acid analogs of SDI molecules can be evaluated by their capacity to be regulated by p53, or other cellular regulators. Alternatively, their capacity to affect cellular proliferation can be directly assayed. For protein analogs of SDI such studies can be accomplished by purifying the mutant protein, and comparing its activity to an SDI molecule. The

analysis of such mutants can also be facilitated through the use of a phage display protein ligand screening system (Lowman, H.B. *et al.*, *Biochem.* 30:10832-10838 (1991); Markland, W. *et al.*, *Gene* 109:13-19 (1991); Roberts, B.L. *et al.*,
5 *Proc. Natl. Acad. Sci. (U.S.A.)* 89:2429-2433 (1992); Smith, G.P., *Science* 228:1315-1317 (1985); Smith, R.P. *et al.*, *Science* 248:1126-1128 (1990), all herein incorporated by reference)). In general, this method involves expressing a fusion protein in
10 which the desired protein ligand is fused to the C-terminus of a viral coat protein (such as the M13 Gene III coat protein, or a lambda coat protein).

Mimetic analogs of naturally occurring SDI molecules may be obtained using the principles of conventional or of rational drug design (Andrews, P.R. *et al.*, In: *Proceedings of the Alfred*
15 *Benzon Symposium*, volume 28, pp. 145-165, Munksgaard, Copenhagen (1990); McPherson, A. *Eur. J. Biochem.* 189:1-24 (1990); Hol, W.G.J. *et al.*, In: *Molecular Recognition: Chemical and Biochemical Problems*, Roberts, S.M. (ed.); Royal Society of Chemistry; pp. 84-93 (1989); Hol, W.G.J., *Arzneim-Forsch.*
20 *39:1016-1018* (1989); Hol, W.G.J., *Angew. Chem. Int. Ed. Engl.* 25:767-778 (1986) all herein incorporated by reference).

In accordance with the methods of conventional drug design, the desired mimetic molecules are obtained by randomly testing molecules whose structures have an attribute
25 in common with the structure of a "native" SDI molecule, or a molecule that interacts with an SDI molecule. The quantitative contribution that results from a change in a particular group of a binding molecule can be determined by measuring the capacity of competition or cooperativity between the native SDI
30 molecule and the putative mimetic.

In one embodiment of rational drug design, the mimetic is designed to share an attribute of the most stable three-dimensional conformation of an SDI molecule. Thus, the mimetic analog of a SDI molecule may be designed to possess
35 chemical groups that are oriented in a way sufficient to cause ionic, hydrophobic, or van der Waals interactions that are similar to those exhibited by the SDI molecule. In a second method of rational design, the capacity of a particular SDI

molecule to undergo conformational "breathing" is exploited. Such "breathing" -- the transient and reversible assumption of a different molecular conformation -- is a well appreciated phenomenon, and results from temperature, thermodynamic factors, and from the catalytic activity of the molecule. Knowledge of the 3-dimensional structure of the SDI molecule facilitates such an evaluation. An evaluation of the natural conformational changes of an SDI molecule facilitates the recognition of potential hinge sites, potential sites at which hydrogen bonding, ionic bonds or van der Waals bonds might form or might be eliminated due to the breathing of the molecule, etc. Such recognition permits the identification of the additional conformations that the SDI molecule could assume, and enables the rational design and production of mimetic analogs that share such conformations.

The preferred method for performing rational mimetic design employs a computer system capable of forming a representation of the three-dimensional structure of the SDI molecule (such as those obtained using RIBBON (Priestle, J., *J. Mol. Graphics* 21:572 (1988)), QUANTA (Polygen), InSite (Biosyn), or Nanovision (American Chemical Society). Such analyses are exemplified by Hol, W.G.J. *et al.* (In: *Molecular Recognition: Chemical and Biochemical Problems*, Roberts, S.M. (ed.); Royal Society of Chemistry; pp. 84-93 (1989)), Hol, W.G.J. (*Arzneim-Forsch.* 39:1016-1018 (1989)), and Hol, W.G.J., *Angew. Chem. Int. Ed. Engl.* 25:767-778 (1986)).

In lieu of such direct comparative evaluations of putative SDI analogs, screening assays may be used to identify such molecules. Such an assay will preferably exploit the capacity of the SDI analog to affect cellular proliferation or quiescence. Alternatively, the molecules may be applied to a column containing a binding ligand, such as p53, Rb, cyclin D, etc., and the capacity of the molecule to bind to the column may be evaluated in comparison to the SDI molecule. Alternatively, a mutated SDI molecule (that inhibits the SDI-mediated inhibition of DNA synthesis) can be administered with a suspected antagonist compound. The cells would in this case be

monitored to determine whether the compound is able to re-establish an inhibition of DNA synthesis.

Such assays are particularly useful for identifying peptide or oligonucleotide fragments or mimetics of SDI molecules, or analogs of such molecules. Thus, for example, one may incubate cells in the presence of either an oligonucleotide or a peptide SDI analog (or fragment) and a suspected antagonist compound. The cells would be monitored in order to determine whether the compound is able to impair the ability of the SDI oligonucleotide to inhibit DNA synthesis. As indicated above, column competition assays could alternatively be conducted. Thus, desired SDI classical and mimetic analogs may be identified by a variety of means.

Significantly, an appreciation of the mechanisms through which SDI molecules mediate their inhibition of DNA synthesis provides an alternative, or complimentary, approach to the isolation and recognition of analogs.

As indicated above, cyclin-dependent kinases play an important role in controlling the process of cellular DNA synthesis (Draetta, G. *et al.*, *Trends Biol. Sci.* 15:378-383 (1990)). The SDI molecules of the present invention may be used to dissect the role of such kinases, and the involvement of such cyclins, and to thereby identify SDI analogs that can be used to inhibit DNA synthesis. For example, the D-type cyclins are believed to play a role in the G1 or S phase of DNA synthesis (Xiong, Y. *et al.*, *Cell* 71:505-514 (1992)). The level of cyclin D/cyl1 protein increases throughout G1, declines during S and G2, and reaches a nadir after mitosis (Matsushime, H. *et al.*, *Cell* 65:701-7139 (1991); Kiyokawa, H. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 89:2444-2447 (1992); Xiong, Y. *et al.*, *Cell* 71:505-514 (1992)).

Xiong, Y. *et al.* (*Cell* 71:505-514 (1992)) reported the existence of a 21 kd polypeptide that associates with cyclin D1 and CDK2. An immunological precipitation method was used in which radiolabelled extracts of cells were incubated in the presence of anti-cyclin antibodies. Proteins that associated with these antibodies were subjected to electrophoresis, and visualized.

The sequence of this 21 kd polypeptide has now been determined, and found to be encoded by SDI-1. Thus, since SDI-1 encode molecules inhibit DNA synthesis, the present invention establishes a biological role for the 21 kd protein (e.g., controlling the transit of the cells from G₁ to S, and from S to G₂. Moreover, since the SDI-1 encoded protein interacts with cyclin D1 and CDK2, the present invention establishes that agents that inhibit or reduce this interaction will be analogs of the SDI molecules.

10 The immunological precipitation method used by Xiong, Y. *et al.* (*Cell* 71:505-514 (1992)) to demonstrate the association of the 21 kd polypeptide and the cyclin D1 and CDK2 molecules may be exploited to determine the mechanism or pathway through which other SDI molecules mediate their inhibitory effect, and thereby permit the identification of other analogs.

15 For example, cells infected with an SDI-2 or SDI-3 sequence, or with antisense molecules for either can be analyzed to determine whether they express any of the proteins that have been previously shown to bind to a cyclin molecule.

20 This can most readily be done by determining whether a particular protein is immunoprecipitated when an extract of treated cells is incubated with an anti-cyclin antibody. Since such a method identifies the molecules with which the SDI molecules interact, it establishes the pathway through which such SDI molecules mediate their inhibitory action. Molecules that impair or effect that pathway are analogs of such SDI molecules. Thus, the methods of the present invention can be used to identify inhibitors of any of the regulators of the cell cycle. Indeed, the SDI-1 protein has been found to interact

25 with CDK4 and CDK5 as well as CDK2. Thus, it is likely that the SDI-1 protein interacts with multiple CDK and cyclin molecules.

Thus, the recognition that SDI molecules exert their control over cellular proliferation through interactions with cyclins and CDK molecules provides an alternate approach to the

35 identification of SDI analogs. In a similar manner, the recognition that other cellular regulators mediate their actions

by regulating SDI transcription or expression provides yet another alternate method for identifying SDI analogs.

For example, the transcription of the SDI-1 gene has been found to be regulated by "tumor suppressor" genes, and most notably by the p53 tumor suppressor gene. Indeed, the "tumor suppressor" capacity of p53 results from its capacity to induce SDI-1 expression, and thereby induce cellular quiescence in tumor cells.

The p53 gene has been previously found to encode a tumor-suppressing protein (Sager, R., *Science* 246:1406-1412 (1989); Finlay, C., *Cell* 57:1083 (1989); Weinberg, R.A., *Scientific Amer.*, Sept. 1988, pp 44-51; Lane, D. *et al.* (*Genes Devel.* 4:1-8 (1990)). The p53 gene has also been found to play a protective role against the transforming effects of Friend erythroleukemia virus (Munroe, D. *et al.* *Oncogene* 2:621 (1988)), and to influence chromosome stability, differentiation and quiescence, and cell proliferation (Sager, R., *Science* 246:1406-1412 (1989)). It has been found that wild type p53 is necessary for cell cycle arrest following ionizing radiation and the constitutive expression of wild type p53 can arrest mammalian cells in G1. The ability to induce cell cycle arrest is thought to be related to p53's tumor suppressor function. The protein encoded by the p53 gene is a nuclear protein that forms a stable complex with both the SV40 large T antigen and the adenovirus E1B 55 kd protein.

Approximately 50% of all tumor cells evidence a mutation that diminishes or obliterates p53 expression. The p53 gene has been implicated as having a role in colorectal carcinoma (Baker, S.J. *et al.*, *Science* 244:217-221 (1989)). Studies have shown that allelic deletions that encompass the p53 locus occurred in over 75% of colorectal carcinomas (Baker, S.J. *et al.*, *Science* 244:217-221 (1989)). The deletion of the region was found to mark a transition from a (benign) adenocarcinoma stage to a (malignant) carcinomatous stage (Vogelstein, B. *et al.*, *New Engl. J. Med.* 319:525 (1988)).

Similar deletions in chromosome 17 have been identified in a wide variety of cancers including breast and lung cancers (Mackay, J. *et al.*, *Lancet* ii:1384 (1988); James, C.D. *et al.*, *Canc.*

Res. 48:5546 (1988); Yakota, J. *et al.*, *Proc. Nat'l. Acad. Sci. (U.S.A.) 84:9252* (1987); Toguchida *et al.*, *Canc. Res. 48:3939* (1988)). A variety of human tumors (brain, colon, breast, lung) are characterized by cells that have lost one of the two normal p53 alleles, and have sustained a point mutation in the remaining p53 allele (Nigro *et al.*, *Nature 342:705-708* (1989)). Fearon *et al.* (*Cell 61:759-767* (1990)) have hypothesized that both point mutations and deletions in the p53 alleles may be required for a fully tumorigenic phenotype. These findings suggest that the p53 gene may have a role in many types of cancers.

Recent evidence has suggested that a mutation in the p53 gene may be responsible for the Li-Fraumeni Syndrome, a rare human genetic disorder (Malkin, D. *et al.*, *Science 250:1233-1238* (1990); Marx, J., *Science 250:1209* (1990), both references herein incorporated by reference). Individuals afflicted with this disease are highly susceptible to several malignant tumors - breast carcinomas, soft tissue sarcomas, brain tumors, osteosarcomas, leukemia, and adrenocortical carcinoma. The disease is also associated with a higher incidence of melanoma, gonadal germ cell tumors, and carcinomas of the lung, pancreas and prostate (Li, F.P. *et al.*, *Ann. Intern. Med. 71:747* (1969); Birch, J.M. *et al.*, *J. Clin. Oncol. 8:583* (1990); Birch, J.M. *et al.*, *Brit. J. Canc. 49:325* (1984); Li, F.P. *et al.*, *Canc. Res. 48:5358* (1988); Williams, W.R. *et al.*, *Familial Canc., 1st Int. Res. Conf. p. 151* (Karger, Basel, 1985); Strong, L.C. *et al.*, *J. Natl. Canc. Inst. 79:1213* (1987)).

Despite the extensive prior characterization of the biological role of the p53 gene, the mechanism through which its gene product mediated its tumor suppressor activity had not been previously elucidated. One aspect of the present invention relates to the discovery of that this mechanism involves SDI-1. Normal p53 protein increases the expression of SDI-1, and such increased expression suppresses cellular proliferation. In tumor cells that lack p53 function, SDI-1 levels are quite low, thus permitting cellular proliferation to occur.

The physiological significance of inhibition of cell proliferation by overexpression of SDI-1 is strengthened by the

finding that SDI-1 can inhibit the kinase activity of cyclin/cdk2 complexes. Addition of a GST-SDI-1 fusion protein to cyclin/cdk2 complexes immunoprecipitated from HeLa cell extracts by cdk2 antisera resulted in half maximal inhibition of histone H1 kinase activity.

Thus, molecules that inhibit the tumor suppressor activity of p53 are antagonists of SDI-1; similarly, molecules that enhance the tumor suppressor activity of p53 are antagonists of SDI-1, and are also encompassed by the present invention.

In normal human cells, SDI-1 has been found to exist as a complex with a cyclin, a CDK, and the proliferating cell nuclear antigen, "PCNA" (Waga, S. *et al.*, *Nature* 369:574-578 (1994), herein incorporated by reference). PCNA is involved in the excision repair pathway through which cells repair damaged DNA. SDI-1 acts to block PCNA's ability to activate DNA polymerase δ . Thus, if cellular DNA is damaged before S phase, the induction of p53 leads to the transcriptional activation of the SDI-1 gene. The expressed SDI-1 protein complexes with CDK/cyclin-mediated DNA replication, and thus permits PCNA to mediate the excision repair of the damage. If the cellular DNA is damaged during S phase, excision repair would lead to increased damage potential. Hence, when damage occurs during S phase, the expressed SDI-1 protein complexes with PCNA to halt the replication process. As demonstrated below (Example 22), a 23 kD protein has been identified that exhibits the characteristics of an inactive, phosphorylated derivative of the SDI-1 protein. This derivative may be involved in the mechanism through which SDI-1 inhibition of PCNA is relieved after the completion of the DNA repair process.

Such an understanding of the interrelationship between SDI-1 and PCNA may be used to identify antagonists or mimetics of SDI-1. Thus, for example, molecules that inhibit the capacity of SDI-1 to complex with PCNA in cells undergoing S phase comprise antagonists and inhibitors of SDI-1 action. Conversely, molecules that enhance the capacity of SDI-1 to complex with PCNA in cells undergoing S phase comprise SDI-1 mimetics.

D. Antagonists of the SDI Molecules

The present invention thus also pertains to antagonists of the SDI molecules. Such antagonists may comprise SDI analogs that compete with, or that inhibit SDI function. Alternatively, 5 such antagonists may comprise analogs of molecules such as cell cyclins or p53, that interact with SDI molecules.

Any of a variety of methods can be used to identify polypeptides or non-proteinaceous molecules that inhibit or repress SDI function. Such molecules can be evaluated to 10 determine whether they compete with normal SDI molecules, or whether their presence in a cell affects the capacity of an SDI molecule to induce a quiescent state. For example, nucleic acid molecules that competitively bind p53 molecules are antagonists of SDI molecules. Such competitors can be readily 15 identified using affinity columns, or by DNase-footprinting methods.

Analogues of p53, or other tumor suppressor proteins, that are capable of interacting with and activating SDI sequences are an additional class of antagonists. Inhibitors of p53 (and 20 other tumor suppressors) are likewise antagonists of the SDI molecules. Such molecules may be obtained by, for example, mutagenizing p53-encoding cDNA, and identifying p53 mutants that retain the capacity to bind to SDI-1 gene sequences or to SDI-1 proteins, but are otherwise inactive. The sequences of 25 the cDNA and genomic forms of the p53 gene have been determined (Pennica, D. *et al.*, *Virology* 134:477-482 (1984); Jenkins, J. *et al.*, *Nature* 312:651-654 (1984); Oren, M. *et al.*, *EMBO J.* 2:1633-1639 (1983); Zahut-Houri, R. *et al.*, *Nature* 306:594-597 (1983), all of which references are herein 30 incorporated by reference).

Alternatively, candidate inhibitors can be provided to a recipient cell and their capacity to impair normal p53 function can be ascertained. For example, such molecules can be tested for their capacity to prevent p53 from forming complexes with 35 the SV40 large T antigen (see, DeCaprio, J.A. *et al.*, *Cell* 54:275-283 (1988); Crawford, L.V., *Int. Rev. Exper. Pathol.* 25:1-50 (1983)).

Similarly, a variety of means can be exploited in order to identify nucleic acid molecules that inhibit or repress SDI-mediated inhibition of DNA synthesis. For example, the SDI nucleic acid sequences can be mutated, and the mutated sequences provided to cells in order to identify cells that do not exhibit an inhibition of DNA synthesis, and which have therefore received the desired mutated SDI sequences. In yet another method, the SDI gene sequences of immortalized cell lines can be evaluated to determine whether they contain mutated SDI genes that have lost the capacity to mediate cellular quiescence. In such manner, it has been determined that some immortalized cells (approximately 10%) carry a mutation in the SDI-1 gene that results in the substitution of arginine at amino acid residue 31 of SDI-1 (in place of the serine residue normally found at this position). Such a finding also implicates residue 31 of SDI-1 as being relevant to the active site or conformation of SDI-1. Since DNA from 12 normal Caucasian donors did not have this SDI-1 substitution, it is unlikely that the Arg31 SDI-1 variant reflects a polymorphism rather than a mutation.

Other mutant SDI proteins have been identified by screening the SDI proteins of various cell lines. Thus, for example, SDI-1 mutants have been identified in which the valine normally found at amino acid residue 54 has been replaced with alanine, or in which the threonine normally found at amino acid residue 80 has been replaced with methionine.

Alternatively, mutated SDI sequences expressed from such nucleic acid molecules can be evaluated for their capacity to bind p53 protein, or the gene products of other tumor suppressor genes such as rb, etc.

In yet another embodiment, "triplex" nucleic acid molecules may be used to provide the desired therapy. A "triplex" molecule is a nucleic acid molecule that is capable of binding to double-stranded DNA in a manner sufficient to impair its transcription. Such an oligonucleotide can be of any length that is effective for this purpose. Preferably, the oligonucleotide will be about 10-30 nucleotides in length, most preferably, about 15-24 nucleotides in length. Triplex

oligonucleotides are disclosed by Hogan, U.S. Patent No. 5,176,996 and by Varma et al., U.S. Patent No. 5,175,266.

5 The triplex oligonucleotides will preferably be about 20 nucleotides or more in length, and designed to bind to region of the SDI-1 gene that has a nucleotide sequence that is either about 2/3 purine or about 2/3 pyrimidine. In designing the sequence of the triplex oligonucleotide, the oligonucleotide is constructed to have a G residue when the complementary location in the target region is a GC base pair and a T residue
10 when the complementary location in the target region is an AT base pair.

The sequence of the SDI-1 gene may differ from that of the cDNA if the gene contains intervening non-translated sequences ("introns"). In one embodiment, the genomic SDI-1
15 sequence is obtained and evaluated for the presence of regions that comport with the above-described preferred ratio of purines to pyrimidines. Such genomic sequences can be obtained by screening genomic libraries with oligonucleotides probes (e.g., 20-50 residues in length) having sequences
20 selected from that of SEQ ID NO:1. Methods for screening genomic libraries are known in the art.

Alternatively, the SDI-1 cDNA sequence can be employed to generate suitable triplex molecules. An analysis of several hundred genes having intervening sequences ("introns") and
25 translated sequences ("exons") has revealed that the intron-exon boundaries have defined upstream and downstream consensus sequences (Mount, S.M., *Nucl. Acids Res.* 10:459-472 (1982), herein incorporated by reference. The excision of the introns from mRNA precursor molecules removes most of these
30 consensus sequences, and fuses the mRNA to create either a "CAGG" or an "AAGG" exon-exon boundary in the mRNA. Thus suitable target regions of the SDI-1 molecule will preferably (1) be at least 20 nucleotides in length; (2) lack CAGG or AAGG sequences and (3) be either about 2/3 purine or about 2/3
35 pyrimidine. Such suitable oligonucleotides can be readily identified by mere inspection of SEQ ID NO:1 (e.g., with reference to the nucleotide positions in SEQ ID NO:1, SEQ ID NO:11-20, SEQ ID NO:121-40, SEQ ID NO:151-70, SEQ ID NO:181-

100, SEQ ID NO:1128-147, SEQ ID NO:1131-150, SEQ ID
NO:1151-170, SEQ ID NO:1241-260, SEQ ID NO:1288-307, SEQ ID
NO:1304-323, SEQ ID NO:1329-348, SEQ ID NO:1334-353, SEQ ID
NO:1361-380, SEQ ID NO:1390-409, SEQ ID NO:1421-440, SEQ ID
5 NO:1497-516, SEQ ID NO:1525-544, SEQ ID NO:1541-560, etc.
comprise some of the suitable target sites within the first 600
nucleotides of SEQ ID NO:1).

In yet another embodiment, the sequences of the SDI
molecules can be used to define "antisense oligonucleotides"
10 that can repress the transcription or translation of an SDI gene
sequence. In general, an "antisense oligonucleotide" is a
nucleic acid (either DNA or RNA) whose sequence is
complementary to the sequence of a target mRNA molecule (or
its corresponding gene) such that it is capable of binding to, or
15 hybridizing with, the mRNA molecule (or the gene), and thereby
impairing (i.e. attenuating or preventing) the translation of the
mRNA molecule into a gene product. To act as an antisense
oligonucleotide, the nucleic acid molecule must be capable of
binding to or hybridizing with that portion of target mRNA
20 molecule (or gene) which mediates the translation of the
target mRNA. Thus, antisense molecules of the present
invention are capable of binding to an SDI nucleic acid molecule
and inhibiting its activity. Antisense oligonucleotides are
disclosed in European Patent Application Publication Nos.
25 263,740; 335,451; and 329,882, and in PCT Publication No.
WO90/00624, all of which references are incorporated herein
by reference.

The present invention is particularly concerned with
those antisense oligonucleotides, especially fragments of the
30 SDI-1, SDI-2, or SDI-3 genes, which are capable of binding to or
hybridizing with mRNA or cDNA molecules that encode an SDI
gene product. Thus, in one embodiment of this invention, an
antisense oligonucleotide that is designed to specifically block
translation of an SDI mRNA transcript can be used to de-
35 repress the inhibition of DNA synthesis in a recipient quiescent
cell.

One manner in which an anti-SDI antisense oligonucleo-
tide may achieve these goals is by having a sequence

complementary to that of the translation initiation region of an SDI mRNA and of sufficient length to be able to hybridize to the mRNA transcript of an SDI gene. The size of such an oligomer can be any length that is effective for this purpose. Preferably, the antisense oligonucleotide will be about 10-30 nucleotides in length, most preferably, about 15-24 nucleotides in length.

Alternatively, one may use antisense oligonucleotides that are of a length that is too short to be capable of stably hybridizing to an SDI mRNA under physiologic, *in vivo* conditions. Such an oligonucleotide may be from about 6-10, or more nucleotides in length. To be used in accordance with the present invention, such an oligonucleotide is preferably modified to permit it to bind to a locus of the translation region of an SDI-encoding mRNA. Examples of such modified molecules include oligonucleotides bound to an antibody (or antibody fragment), or other ligand (such as a divalent crosslinking agent (such as, for example, trimethylpsoralin, 8-methoxypsoralin, etc.) capable of binding to a single-stranded SDI mRNA molecules.

In yet another embodiment, SDI-1 antisense molecules may be designed such that they hybridize to, and stabilize, an unstable segment of the SDI-1 mRNA. Such molecules would thus enhance the transcription and translation of SDI-1 in a cell, and lead to an increased ability to inhibit DNA replication. Such molecules may be used to treat cancer, and other diseases or conditions characterized by hyperproliferation.

An anti-SDI antisense oligonucleotide bound to one reactive group of a divalent crosslinking agent (such as psoralin (for example, trimethylpsoralin, or 8-methoxypsoralin) adduct would be capable of crosslinking to an SDI mRNA upon activation with 350-420 nm UV light. Thus, by regulating the intensity of such light (as by varying the wattage of the UV lamp, by increasing the distance between the cells and the lamp, etc.) one may control the extent of binding between the antisense oligonucleotide and an SDI mRNA of a cell. This, in turn, permits one to control the degree of attenuation of SDI gene expression in a recipient cell.

In general, the antisense oligomer is prepared in accordance with the nucleotide sequence of an SDI gene, and most preferably in accordance with the nucleotide sequence of SDI-1 provided in Figures 5A-5D. The sequence of the
5 antisense oligonucleotide may contain one or more insertions, substitutions, or deletions of one or more nucleotides provided that the resulting oligonucleotide is capable of binding to or hybridizing with the above-described translation locus of either an SDI mRNA, cDNA or an SDI gene itself.

10 Any means known in the art to synthesize the antisense or triplex oligonucleotides of the present invention may be used (Zamechik *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 83:4143 (1986); Goodchild *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 85:5507 (1988); Wickstrom *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 85:1028; Holt,
15 J.T. *et al.*, *Molec. Cell. Biol.* 8:963 (1988); Gerwitz, A.M. *et al.*, *Science* 242:1303 (1988); Anfossi, G., *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 86:3379 (1989); Becker, D., *et al.*, *EMBO J.* 8:3679 (1989); all of which references are incorporated herein by reference). Automated nucleic acid synthesizers may be
20 employed for this purpose. In addition, desired nucleotides of any sequence can be obtained from any commercial supplier of such custom molecules.

Most preferably, the antisense or triplex oligonucleotides of the present invention may be prepared using solid phase
25 "phosphoramidite synthesis." The synthesis is performed with the growing nucleotide chain attached to a solid support derivatized with the nucleotide which will be the 3'-hydroxyl end of the oligonucleotide. The method involves the cyclical synthesis of DNA using monomer units whose 5'-hydroxyl group
30 is blocked (preferably with a 5'-DMT (dimethoxytrityl) group), and whose amino groups are blocked with either a benzoyl group (for the amino groups of cytosine and adenosine) or an isobutyryl group (to protect guanosine). Methods for producing such derivatives are well known in the art.

35 In yet another embodiment, ribozymes can be employed as inhibitors of SDI-mediated inhibition. Ribozymes (RNA enzymes) are catalytic RNA sequences (containing no protein) that can cleave RNA target molecules with which they

hybridize (Cech, T. *et al.*, *Cell* 27: 487 (1981); Cech, T., *Science* 236: 1532-1539 (1987); Cech, T. *et al.*, *Ann. Rev. Biochem.* 55: 599-630 (1986); James, W., *Antivir. Chem. Chemother.* 2: 191-214 (1991)). Often the substrate is part of the ribozyme itself.

5 An artificial ribozyme can be designed to specifically cleave a target RNA by flanking sequences complementary to the target (Haseloff, J. *et al.*, *Nature* 334: 585-591 (1988); Cameron, F. *et al.*, *Proc. Natl. Acad. Sci. USA* 86: 9139-9143 (1989); James, W., *Antiviral Chemistry & Chemotherapy* 2: 191-10 214 (1991). The minimum requirement for cleavage within the target RNA is the location of a suitable three base sequence GUC, GUA, or GUU preceding the cleavage site. Artificial ribozymes having a characteristic "hammerhead" secondary structure have been designed by Haseloff, J. *et al.* (*Nature* 334: 15 585-591 (1988); Jeffries, A. *et al.*, *Nucleic Acids Res.* 17: 1371-1377 (1989); Gerlach *et al.* WO Patent Application WO89/05852 (1989); Goodchild, J. *et al.*, *Arch. Biochem. Biophys.* 284: 386-391 (1991); James, W., *Antivir. Chem. Chemother.* 2: 191-214 (1991)).

20 E. Protagonists of the SDI Molecules

The present invention thus also pertains to protagonists of the SDI molecules. As used herein, a "protagonist" of an SDI molecule is a molecule that enhances or increases the biological activity of an SDI molecule.

25 Since p53 is an inducer of SDI expression, it, or a nucleic acid encoding p53, or biologically active fragments of either, may be provided to cells in conjunction with an SDI molecule in order to obtain increased SDI expression.

The present invention also provides SDI protagonists 30 other than the naturally occurring tumor suppressor proteins. Such protagonists may comprise SDI analogs or may comprise non-analog molecules that interact with the cellular molecules that interact with SDI molecules. Thus, mutant forms of the p53 protein having enhanced SDI-activating capacity comprise 35 one illustrative SDI protagonist. Such molecules may be produced by mutating the p53 gene, and then selecting muteins

that effect more rapid or more extensive induction of SDI-1 activity than the normal p53 protein.

Similarly, SDI protagonists can be identified through the use of screening assays in which, for example, a candidate molecule is provided to a recipient cell along with an SDI molecule, and the capacity of the candidate molecule to enhance SDI expression is monitored. The above-described methods of rational mimetic design can be used to define SDI protagonists.

10 **F. Antibodies to SDI Molecules**

One aspect of the present invention concerns antibodies to SDI proteins and protein fragments and the diagnostic and therapeutic uses of such antibodies.

The above-described SDI proteins and protein fragments may be used to elicit the production of antibodies, single-chain antigen binding molecules, or other proteins capable of binding an SDI epitope. Such antibodies may be polyclonal or monoclonal, and may comprise intact immunoglobulins, of antigen binding portions of immunoglobulins (such as (F(ab'), F(ab')₂) fragments, or single-chain immunoglobulins producible, for example, via recombinant means.

Murine monoclonal antibodies are particularly preferred. BALB/c mice are preferred for this purpose, however, equivalent strains may also be used. The animals are preferably immunized with approximately 25 µg of affinity purified SDI protein (or fragment thereof) that has been emulsified a suitable adjuvant (such as TiterMax adjuvant (Vaxcel, Norcross, GA)). Immunization is preferably conducted at two intramuscular sites, one intraperitoneal site, and one subcutaneous site at the base of the tail. An additional i.v. injection of approximately 25 µg of antigen is preferably given in normal saline three weeks later. After approximately 11 days following the second injection, the mice may be bled and the blood screened for the presence of anti-SDI antibodies. Preferably, a direct binding ELISA is employed for this purpose.

Most preferably, the mouse having the highest antibody titer is given a third i.v. injection of approximately 25 µg of

SDI protein or fragment. The splenic leukocytes from this animal may be recovered 3 days later, and are then permitted to fuse, most preferably, using polyethylene glycol, with cells of a suitable myeloma cell line (such as, for example, the
5 P3X63Ag8.653 myeloma cell line). Hybridoma cells are selected by culturing the cells under "HAT" (hypoxanthine-aminopterin-thymine) selection for about one week. The resulting clones may then be screened for their capacity to produce monoclonal antibodies ("mAbs) to SDI protein,
10 preferably by direct ELISA.

In one embodiment, anti-SDI-1 monoclonal antibodies are isolated using the above-described SDI-1 fusions as immunogens and to facilitate screening. Thus, for example, a group of mice can be immunized using the GST-SDI-1 fusion
15 protein emulsified in Freund's complete adjuvant (approximately 50 µg of antigen per immunization). At three week intervals, an identical amount of antigen is emulsified in Freund's incomplete adjuvant and used to immunize the animals. Ten days following the third immunization, serum
20 samples are taken and evaluated for the presence of antibody. If antibody titers are too low, a fourth booster can be employed. Polysera capable of binding SDI-1 at 1:5,000 dilution can be obtained using this method.

In a preferred procedure for obtaining monoclonal
25 antibodies, the spleens of the above-described immunized mice are removed, disrupted and immune splenocytes are isolated over a ficoll gradient. The isolated splenocytes are fused, using polyethylene glycol with Balb/c-derived HGPRT (hypoxanthine guanine phosphoribosyl transferase) deficient
30 P3x63xAg8.653 plasmacytoma cells. The fused cells are plated into 96 well microtiter plates and screened for hybridoma fusion cells by their capacity to grow in culture medium supplemented with hypoxanthine, aminopterin and thymidine for approximately 2-3 weeks. On average, out of every 10^6
35 spleen cells subjected to fusion yields a viable hybridoma. A typical spleen yields $5-10 \times 10^7$ spleen cells.

Hybridoma cells that arise from such incubation are preferably screened for their capacity to produce an

immunoglobulin that binds to SDI-1. An indirect ELISA may be used for this purpose. In brief, the supernatants of hybridomas are incubated in microtiter wells that contain immobilized GST-SDI-1. After washing, the titer of bound immunoglobulin is determined using a goat anti-mouse antibody conjugated to horseradish peroxidase. After additional washing, the amount of immobilized enzyme is determined (for example through the use of a chromogenic substrate). Such screening is performed as quickly as possible after the identification of the hybridoma in order to ensure that a desired clone is not overgrown by non-secreting neighbors. Desirably, the fusion plates are screened several times since the rates of hybridoma growth vary. In a preferred sub-embodiment, a different antigenic form of SDI-1 may be used to screen the hybridoma. Thus, for example, the splenocytes may be immunized with the GST-SDI-1 fusion, but the resulting hybridomas can be screened using a [His]₆ fusion, such as that having the leader sequence of SEQ ID NO:4.

As discussed below, such antibody molecules or their fragments may be used for either diagnostic or therapeutic purposes. Where the antibodies are intended for diagnostic purposes, it may be desirable to derivatize them, for example with a ligand group (such as biotin) or a detectable marker group (such as fluorescent group, a radioisotope or an enzyme).

Where the antibodies or their fragments are intended for therapeutic purposes, it may be desirable to "humanize" them in order to attenuate any immune reaction. Humanized antibodies may be produced, for example by replacing an immunogenic portion of an antibody with a corresponding, but non-immunogenic portion (i.e. chimeric antibodies) (Robinson, R.R. *et al.*, PCT Patent Publication PCT/US86/02269; Akira, K. *et al.*, European Patent Application 184,187; Taniguchi, M., European Patent Application 171,496; Morrison, S.L. *et al.*, European Patent Application 173,494; Neuberger, M.S. *et al.*, PCT Application WO 86/01533; Cabilly, S. *et al.*, European Patent Application 125,023; Better, M. *et al.*, *Science* 240:1041-1043 (1988); Liu, A.Y. *et al.*, *Proc. Natl. Acad. Sci. USA* 84:3439-3443 (1987); Liu, A.Y. *et al.*, *J. Immunol.* 139:3521-3526 (1987); Sun, L.K. *et al.*, *Proc. Natl. Acad. Sci.*

USA 84:214-218 (1987); Nishimura, Y. *et al.*, *Canc. Res.* 47:999-1005 (1987); Wood, C.R. *et al.*, *Nature* 314:446-449 (1985)); Shaw *et al.*, *J. Natl. Cancer Inst.* 80:1553-1559 (1988); all of which references are incorporated herein by reference).

- 5 General reviews of "humanized" chimeric antibodies are provided by Morrison, S.L. (*Science*, 229:1202-1207 (1985)) and by Oi, V.T. *et al.*, *BioTechniques* 4:214 (1986); which references are incorporated herein by reference).

10 In one therapeutic embodiment, chimeric bivalent antibodies are employed which contain two different Fab regions, such that the antibody is capable of binding to an SDI epitope (via the first such Fab region) and to a "non-SDI epitope" (i.e. an epitope of a protein other than an SDI protein) (via the second such Fab region). In one embodiment, such
15 "non-SDI epitopes" are selected such that the chimeric molecule can bind to cellular receptors, such as hormone receptors, immune response receptors, etc. Particularly preferred non-SDI receptors include cellular antigens that are indicative of neoplasia, such as antigens associated with
20 leukemia (Seon *et al.*, *Proc. Natl. Acad. Sci., USA* 80:845 (1983); Aota *et al.*, *Cancer Res.* 43:1093 (1983); Royston *et al.*, *Transplan. Proc.* 13:761 (1981)); colon cancer (Koprowski *et al.*, U.S. Patent No. 4,349,528; Sakamoto *et al.*, European Patent Publication No. 119556; Herlyn *et al.*, *Proc. Natl. Acad. Sci., USA*
25 76(3):1438 (1979); Magnani *et al.*, *Science* 212:55 (1981)); lung cancer (Cuttitta *et al.*, *Proc. Natl. Acad. Sci., USA* 78:4591 (1981)); breast cancer (Colcher *et al.*, *Proc. Natl. Acad. Sci., USA* 78:3199 (1981); Schlom *et al.*, *Proc. Natl. Acad. Sci., USA* 77:6841 (1980)) and other cancers (See, Lloyd, "Human Tumor
30 Antigens: Detection and Characterization with Monoclonal Antibodies," In: Herberman, ed., *Basic and Clinical Tumor Immunology* 1:159-214, Nijoff, Boston (1983).

G. Cellular Receptors of SDI Molecules

35 One aspect of the present invention concerns cellular receptors of SDI molecules, and in particular cellular receptors of SDI-1, for facilitating the delivery of SDI into target cells.

In one embodiment, such delivery can be accomplished by expressing the SDI molecule as a fusion with a lymphokine, hormone, prohormone, or other molecule that possesses a cellular receptor or a cell-surface ligand that is capable of binding a receptor. Most preferably, this is accomplished by ligating a polynucleotide that encodes an SDI molecule (such as SDI-1 cDNA) to a polynucleotide that encodes the protein which is to be recognized and bound by the receptor or cell-surface ligand, and then expressing the desired fusion protein via recombinant means. The fusion protein need not contain the complete sequence of the receptor binding molecule, but may contain only an amount of protein sufficient to permit the desired binding.

In one sub-embodiment, the receptor-binding molecule is selected such that the relevant receptor is present on all or most cells. Examples of such molecules include most peptide hormones (such as growth hormone, insulin, etc.) which bind to their respective receptors, transferrin which binds to the transferrin receptor, Apo-B protein which binds to the low density lipoprotein (LDL) receptor, etc. Alternatively, the SDI fusion protein may be selected such that molecule is capable of being adsorbed by only certain tissue-types or subtypes. Such specificity may be obtained through the use of molecules that are bound to receptors or ligands that are present only on certain populations of cells (such as liver cells, leukocytes, endothelial cells, etc.). Examples of such molecules include proteins such as glucagon, gastrin, certain pituitary hormones (TSH, FSH, etc.), erythropoietin, interleukins, granulocyte-macrophage colony-stimulating factor, neurotrophic proteins, etc. Additionally, proteins capable of binding to cell-surface proteins such as CD4, ICAM-1, selectins, ELAMS, LFA-1, etc. may be used.

For example, since ICAM-1 (Simmons, D. *et al.*, *Nature* 331:624-627 (1988); Staunton, D.E. *et al.*, *Cell* 52:925-933 (1988); Staunton, D.E. *et al.*, *Cell* 61:243-254 (1990)) is an endothelial cell-surface ligand for leukocytes that express a CD18/CD11 heterodimer (such as LFA-1, etc.) an ICAM-1-SDI fusion molecule would target hematopoietic cells such as

lymphocytes. Similarly, a CD4-SDI-1 fusion would be targeted to CD4+ T cells, and could be used to deliver SDI to such T cells. An LFA-1-SDI-1 fusion would target endothelial cells and certain other cell types. A glucagon-SDI fusion could be used to target liver cells, etc.

In another embodiment, the SDI molecule can be conjugated to a non-protein that can undergo specific binding with a cellular receptor. Examples of such molecules include epinephrine, norepinephrine or histamine derivatives, prostaglandins, etc.

In yet another embodiment, an endogenous cellular receptor that is capable of binding an SDI molecule may be exploited to facilitate the delivery of SDI into a target cell. Such a receptor molecules can be obtained using the above-described SDI proteins and protein fragments. In one method for obtaining the SDI receptor, a DNA (or more preferably, a cDNA) library is produced, preferably from cells that express SDI protein. The cDNA fragments are cloned into an expression plasmid which is then introduced into immortalized or tumor cells. The cells are then incubated in the presence of labeled SDI-1, and evaluated for clones that adsorb the SDI-1 to the cell surface, and that exhibit a renewed quiescent or senescent state. Plasmids that encode cellular receptors are then recovered from such clones.

SDI receptor proteins can also be obtained by expressing cDNA clones in bacteria or other hosts, and then determining whether such clones produce proteins that are capable of binding SDI-1. In one preferred sub-embodiment, the cDNA is incorporated into a phage display vector (Lowman, H.B. *et al.*, *Biochem.* 30:10832-10838 (1991); Markland, W. *et al.*, *Gene* 109:13-19 (1991); Roberts, B.L. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 89:2429-2433 (1992); Smith, G.P., *Science* 228:1315-1317 (1985); Smith, R.P. *et al.*, *Science* 248:1126-1128 (1990), all herein incorporated by reference)). As indicated above, this method involves expressing a fusion protein in which the desired protein ligand is fused to the C-terminus of a viral coat protein (such as the M13 Gene III coat protein, or a lambda coat protein). The phage vectors are then grown to form a library of

phage that possess different fusion proteins. The library is then incubated in the presence of immobilized SDI-1 fusion protein having a glutathione S-transferase glutathione binding sequence as its amino terminus. Phage that display cellular
5 receptors of SDI-1 are retained by the immobilized SDI-1 fusion protein, and can be recovered by washing the column with glutathione.

In an alternate method of obtaining the SDI receptor, a cellular extract is obtained and incubated in the presence of
10 SDI-1, especially an SDI-1 fusion protein having a glutathione S-transferase glutathione binding sequence as its amino terminus. Proteins that bind to SDI-1 comprise cellular receptor protein.

When desired, the receptor molecule can be solubilized to
15 form a soluble (i.e. not membrane bound) receptor molecule by truncating the protein domains responsible for anchoring the receptor to the cellular membrane.

20 **IV. Uses of the SDI Molecules of the Present Invention and their Inhibitors**

A. Induction of Senescence or Quiescence

Molecules capable of inhibiting SDI function, when provided to a recipient cell cause the immortalization of the cell, and thereby permit the establishment of a permanent cell
25 line. The antisense, ribozyme and other SDI inhibitor molecules of the present invention may thus be used to immortalize valuable cell types (such as primary tissue culture cells, etc.) which would otherwise have a transient period of proliferative viability. They may thus be used for research or to permit or
30 facilitate the accumulation of large numbers of cells, as for organ or tissue grafts or transplants. In one embodiment, therefore, the agents of the present invention may be used in conjunction with methods for organ or tissue culture to facilitate such methods. Such molecules may alternatively be
35 used to effect the immortalization of immunoglobulin producing cells, or cells that produce important biologicals, such as hormones (insulin, growth hormone, IGF, etc.), immune

system modifiers (such as interferons, adhesion molecules, lymphokines, etc.).

Such inhibitory nucleic acid molecules will preferably have nucleotide sequences that are complementary to the sequences of the SDI molecules, and most preferably will be complementary to the sequence of regions or all of the SDI-1 gene. When such oligonucleotides are provided to recipient cells, the immortalization of the cell line occurs. Alternatively, the antibodies of the present invention may be used to inhibit SDI activity (e.g., to prevent SDI in a fluid (such as blood) from mediating the quiescence of cells that are in contact with the fluid).

B. Diagnostic Uses

A major use of the molecules of the present invention lies in their capacity to diagnose the presence and predisposition to cancer. Since the absence of SDI-1 expression is the mechanism through which p53-dependent cancers mediate tumorigenicity, assays of cellular SDI-1 expression can be used to diagnose the presence and severity of human cancers. For example, the Li-Fraumeni Syndrome is associated with a particular set of mutations in exon 7 of the p53 gene (Malkin, D. *et al.*, *Science* 250:1233-1238 (1990), herein incorporated by reference). Cells of Li-Fraumeni patients do not produce detectable SDI-1 mRNA or SDI-1 protein. Thus, a diagnosis of this disease may be made using hybridization assays, or immunoprecipitation protocols that measure SDI-1 mRNA or protein levels.

As indicated, approximately 50% of human tumors fail to express normal p53 protein. Thus, assays for p53 activity in biopsy samples is can be used to assess the presence of tumors. Such assays can be readily accomplished using the SDI molecules of the present invention, especially the SDI-1 gene sequences, and their fragments. Since p53 is an inducer of SDI expression, the detection of SDI-1 molecules or mRNA in a biopsy material is suggestive of the normal expression of the p53 gene.

The anti-SDI antibodies of the present invention may be used in an immunoassay to assess the presence of SDI in a cell, tissue or fluid. Any of a wide array of immunoassays formats may be used for this purpose (Fackrell, *J. Clin. Immunoassay* 8:213-219 (1985)), Yolken, R.H., *Rev. Infect. Dis.* 4:35 (1982);
5 Collins, W.P., In: *Alternative Immunoassays*, John Wiley & Sons, NY (1985); Ngo, T.T. *et al.*, In: *Enzyme Mediated Immunoassay*, Plenum Press, NY (1985)). The capacity to detect and/or measure SDI presence provides a highly desirable means for
10 assessing the presence or severity of a tumor. Thus, for example, the absence of SDI in a particular tumor indicates that the tumor is more susceptible to metastasis than an SDI-expressing tumor. In one embodiment, the antibodies of the present invention are employed to measure the solubilized SDI
15 molecules of a sample. The methods of the present invention may, however, be used *in situ* to permit the detection and analysis of SDI present within a biopsied sample.

The simplest immunoassay involves merely incubating an antibody that is capable of binding to a predetermined target
20 molecule with a sample suspected to contain the target molecule. The presence of the target molecule is determined by the presence, and proportional to the concentration, of any antibody bound to the target molecule. In order to facilitate the separation of target-bound antibody from the unbound
25 antibody initially present, a solid phase is typically employed. Thus, for example the sample can be passively bound to a solid support, and, after incubation with the antibody, the support can be washed to remove any unbound antibody.

In more sophisticated immunoassays, the concentration
30 of the target molecule is determined by binding the antibody to a support, and then permitting the support to be in contact with a sample suspected of containing the target molecule. Target molecules that have become bound to the immobilized antibody can be detected in any of a variety of ways. For example, the
35 support can be incubated in the presence of a labeled, second antibody that is capable of binding to a second epitope of the target molecule. Immobilization of the labeled antibody on the support thus requires the presence of the target, and is

proportional to the concentration of the target in the sample. In an alternative assay, the target is incubated with the sample and with a known amount of labeled target. The presence of target molecule in the sample competes with the labeled target molecules for antibody binding sites. Thus, the amount of labeled target molecules that are able to bind the antibody is inversely proportional to the concentration of target molecule in the sample.

In general, immunoassay formats employ either radioactive labels ("RIAs") or enzyme labels ("ELISAs"). RIAs have the advantages of simplicity, sensitivity, and ease of use. Radioactive labels are of relatively small atomic dimension, and do not normally affect reaction kinetics. Such assays suffer, however, from the disadvantages that, due to radioisotopic decay, the reagents have a short shelf-life, require special handling and disposal, and entail the use of complex and expensive analytical equipment. RIAs are described in *Laboratory Techniques and Biochemistry in Molecular Biology*, by Work, T.S., et al., North Holland Publishing Company, NY (1978), with particular reference to the chapter entitled "An Introduction to Radioimmune Assay and Related Techniques" by Chard, T., incorporated by reference herein.

ELISAs have the advantage that they can be conducted using inexpensive equipment, and with a myriad of different enzymes, such that a large number of detection strategies -- colorimetric, pH, gas evolution, etc. -- can be used to quantitate the assay. In addition, the enzyme reagents have relatively long shelf-lives, and lack the risk of radiation contamination that attends to RIA use. ELISAs are described in *ELISA and Other Solid Phase Immunoassays* (Kemeny, D.M. et al., Eds.), John Wiley & Sons, NY (1988), incorporated by reference herein.

C. Therapeutic Uses

The molecules of the present invention also possess therapeutic utility. A use is said to be therapeutic if it alters a physiologic condition. A non-therapeutic use is one which alters the appearance of a user. The agents of the present

invention may be used topically or systemically for a therapeutic or non-therapeutic purpose, such as, for example, to counter the effects of aging, for example on skin tone, color, texture, etc., or on the degeneration of cells, tissue or organs, such as lymphocytes, vascular tissue (such as arteries, arterioles, capillaries, veins, etc.), liver, kidney, heart and other muscle, bone, spleen, etc. The agents of the present invention may be employed to rejuvenate such cells, tissue or organs. Thus, they may be used in pharmaceuticals, and the like, which may comprise, for example, an antisense oligonucleotide, or its equivalent, and a lipophilic carrier or adjunct, preferably dissolved in an appropriate solvent. Such a solvent may be, for example, a water-ethanol mixture (containing 10% to 30% v/v or more ethanol. Such preparations may contain 0.001% to 1.0% of the antisense oligonucleotide. Suitable carriers, adjuncts and solvents are below.

1. Treatment of Cancer and Other Diseases

SDI nucleic acid molecules, their fragments, encoded proteins and polypeptides, and analogs have use in inducing a senescent or quiescent state in a recipient cell. Such induction is desirable in the treatment of age-related disorders (Martin, G.M., *Genome* 31:390 (1989); Roe, D.A., *Clin. Geriatr. Med.* 6:319 (1990); Mooradian, A.D., *J. Amer. Geriatr. Soc.* 36:831 (1988); Alpert, J.S., *Amer. J. Cardiol.* 65:23j (1990)); Alzheimer's disease (Terry, R.D., *Monogr. Pathol.* 32:41 (1990); Costall, B. *et al.*, *Pharmacopsychiatry* 23:85 (1990)); asthenia and cachexia (Verdery, R.B., *Geriatrics* 45:26 (1990)), or diseases or conditions in which rapid cellular proliferation is undesirable. In this respect, the agents of the present invention can be used therapeutically to suppress the rapid proliferation of tumor or tumorigenic cells. Thus, in particular, the molecules of the present invention may be used in the treatment of cancer, particularly liver, pancreatic, kidney, lung, stomach, breast, uterine, colon, skin, glioma, lymphatic, prostate, hepatobiliary cancer and malignant melanoma. Indeed, as discussed below, SDI-1 has broad activity in suppressing the proliferation of tumor cells, such as breast, lung, hepatic and glioma tumor

lines. Remarkably, the SDI molecules of the invention have the ability to mediate the differentiation of cancer cells (especially malignant melanoma cells) into non-cancerous cells.

5 In one embodiment, such treatment is accomplished by providing SDI-1 protein or protein fragments to tumor cells. Such protein may be provided directly, since SDI-1 appears to be capable of directly entering tumor cells. Alternatively, SDI-1 may be provided in liposomes, viral sheaths, or other
10 vehicles. In a second embodiment, gene sequences that encode SDI-1 or fragments of SDI-1 may be provided as a gene therapy for cancer.

In the case of melanoma or other skin cancers, the SDI molecules of the present invention may be provided topically,
15 in an emollient, etc. (preferably formulated with a UV-adsorbing compound, such as p-aminobenzoic acid (PABA).

The SDI molecules of the present invention, particularly when formulated in a liposomal drug delivery vehicle, can be used to treat bladder cancer. Additional cancer applications
20 for the SDI molecules of the invention include the inhibition of endothelial cell replication (antiangiogenesis) to prevent neovascularization of tumors, and targeted gene delivery via tumor specific molecules to halt cell growth or induce apoptosis.

25 The SDI molecules of the present invention may be used alone, or in combination with other conventional chemotherapeutic agents to decrease the effective concentrations that would otherwise be required in order to achieve a therapeutic effect.

30 Indeed, the SDI-1 protein and nucleic acid molecules of the present invention have significant utility when used as an adjunct to conventional chemotherapeutic agents. In one embodiment, the SDI-1 molecules are administered to tumor cells, thereby enhancing the efficacy of the chemotherapeutic agents. In an alternate or complementary embodiment, the SDI-1
35 molecules are provided (or additionally provided) sub-systemically (e.g., locally, or to specific organs or tissue, or

regionally) in order to insulate non-tumor cells from the cytotoxic effects of the chemotherapeutic agents.

The premise of chemotherapy is that cancer cells grow more rapidly than normal cells, and hence are more sensitive to cytotoxic agents than normal cells. Each administration of a chemotherapeutic agent kills a percentage of the existing tumor cells, such that multiple administrations are generally needed in order to completely eliminate a tumor (Tenenbaum, L., In: "Cancer Chemotherapy and Biotherapy A Reference Guide," W.B. Saunders Company, Philadelphia, pp. 3-13 (1994)).

As indicated above, in one embodiment, the SDI-1 molecules of the present invention may be used to increase the sensitivity of cancer cells to chemotherapeutic agents, and thus permit the elimination of a tumor using lower doses and/or fewer doses of the chemotherapeutic agent/ Such increased sensitivity can be obtained, for example, by providing a SDI-1 protein (or nucleic acid molecules that express SDI-1) to a patient in concert with the administration of the chemotherapeutic agent. Such administration serves to inhibit the replication of the cancer cells (the replication of normal cells is also inhibited by the SDI-1 molecules, however, such inhibition is largely immaterial since normal cells proliferate far more slowly than cancer cells). After the SDI-1 molecules are provided to the patient, such administration is terminated or diminished. The effect of such transient or diminishing administration is to synchronize the cancer cells to the same stage in the cell cycle (i.e. to freeze the cells, for example, in the G₁ phase of the cell cycle). Such synchronization significantly increases the sensitivity of the cancer cells to chemotherapeutic agents.

Because such synchronization provides a means for maximizing the percentage of cells that are in a particular phase of the cell cycle at the time of the administration, the administration of SDI-1 molecules enhances the clinical efficacy of chemotherapeutic agents that exert their effect during a specific phase or set of phases of the cell cycle. For example, mitotic inhibitors such as vinca alkaloids (e.g., vincristine, vinblastine, vindesine, etc.), podophyllum

derivatives (e.g., etoposide, teniposide, etc.), taxoids (e.g., taxol, docetaxel, etc.) act during the M phase of the cell cycle by interfering with the formation of the mitotic spindle. Because only a fraction of tumor cells are in M phase at any given time, such drugs must generally be provided in repeated administrations rather than in a single large dose. By treating the cells with SDI-1 molecules, it is possible to synchronize the tumor cells, such that all (or a large fraction) of the cells will be at M phase at the same time. Hence, such SDI-1 administration permits one to employ mitotic inhibitors more effectively.

In a similar manner, antimetabolites such as the folate antagonists (e.g., methotrexate, etc.), purine analogs (e.g., cladribine, fludarabine phosphate, pentostatin, etc.), purine antagonists (e.g., 6-mercaptopurine, 6-thioguanine, etc.) and pyrimidine antagonists (e.g., 5-fluorouracil, 5-fluorodeoxyuridine, cytarabine, etc.) act on cells in S phase. The efficacy of these agents may be enhanced through the adjunct use of SDI-1 molecules.

Such adjunct administration may also be used to improve the selectivity or efficacy of cell cycle phase non-specific chemotherapeutic agents (such as antitumor antibiotics, hydroxyurea, procarbazine, hormones or hormone antagonists, etc.) Despite the observed non-specificity of such agents relative to the cell cycle phase of tumor cells, it is highly probable that synchronization of tumor cell phase will increase the effectiveness of the chemotherapy.

In accordance with the second embodiment, the SDI-1 molecules of the present invention may be used sub-systemically to prevent or to attenuate damage to normal cells. For example, one side effect of conventional cancer chemotherapy is the damage to rapidly growing tissue such as the hair follicles. This damage results in hair loss (alopecia) to affected patients. Despite the transience of such loss, it exacerbates the psychological trauma, discomfort and depression associated with cancer chemotherapy. Such hair loss is thus of significant clinical interest.

The SDI-1 protein or nucleic acid molecules of the present invention may be used to attenuate or prevent damage or death of hair follicles, and thus provide a treatment for hair loss incident to chemotherapy or age. In this embodiment, the SDI-1 molecules would be locally applied (e.g., topically, transdermally, or intradermally to the scalp, etc.). Such administration will inhibit follicular growth, and arrest the cells, for example, at G1. The administration will thus desensitize the hair follicles to damage caused by a subsequent administration of a conventional chemotherapeutic agent.

The SDI molecules of the present invention may also be used to treat mucositis (mouth ulcers) that arise as an unavoidable side-effect of chemotherapy.

The necessity of providing prompt chemotherapy to pregnant cancer patients jeopardizes their developing fetuses, and hence present medical practice must carefully weigh the benefits of early cancer treatment with the potential harm that such treatment might cause to the fetus. The SDI-1 protein or nucleic acid molecules of the present invention may be used to attenuate or prevent damage to developing fetuses in pregnant women who must undergo chemotherapy during their pregnancy. The SDI-1 protein may be locally provided via injection or infusion into the fetal bloodstream, or into the amniotic fluid which bathes the fetus. Preferably, such local administration is conducted prior to or simultaneously with the administration of a chemotherapeutic agent to the mother. The administration of the SDI-1 molecules insulates the fetus from the cytotoxic effects of the chemotherapy.

A large number of non-cancer diseases can also be treated with the SDI molecules of the present invention. The SDI molecules may be used to treat the skin disorder, psoriasis. Particularly when administered topically to treat psoriasis, the use of the SDI molecules of the present invention can limit the hyperproliferative growth of cells involved in psoriasis with minimal cytotoxic side effects. Rheumatoid arthritis, a debilitating autoimmune disease, may also be treated with the SDI-1 molecules of the invention.

The SDI molecules of the invention may be used to mediate or accelerate wound healing of both acute wounds (e.g., lacerations, punctures, surgery, etc.) or chronic wounds (e.g., diabetic ulcers, venous ulcers, decubitus pressure ulcers).

5 The molecules of the present invention may be used to treat restenosis incident to angioplasty. The term "stenosis" denotes a narrowing or constriction of a duct or canal. A variety of disease processes, such as atherosclerotic lesions, immunological reactions, congenital deformities, etc., can lead
10 to the stenosis of coronary arteries and thus to myocardial ischemia. Percutaneous transluminal coronary angioplasty (PTCA), the insertion and partial inflation of a balloon catheter into a stenotic vessel to effect its repair, has been extensively used to treat stenosis. The major limitation of PTCA is
15 "restenosis" (i.e. the re-constriction) of the vascular lesion (Liu, M.W. *et al.*, *Circulation* 79:1374-1386 (1989), herein incorporated by reference). Restenosis has been found to occur in 30% to 40% of angioplasty patients within 6 months of the procedure (Califf, R.M. *et al.*, *J. Amer Col. Cardiol.* 17:2B-13B
20 (1991), McBride, W. *et al.*, *N. Engl. J. Med.* 318:1734-1737 (1988)). Restenosis develops so rapidly that it may be considered a form of accelerated atherosclerosis induced by injury. The significance of the high restenosis rate is compounded by the present inability to predict with a high
25 degree of certainty which patients, vessels, or lesions will undergo restenosis. Indeed, arteries that are widely patent 2 days after PTCA, free of obstructive thrombus, have exhibited restenosis at catheterization 4-6 months later (Liu, M.W. *et al.*, *Circulation* 79:1374-1386 (1989)).

30 Glaucomas can also be treated with the SDI molecules of the present invention. "Glaucomas" are a family of debilitating eye diseases that are each characterized by a progressive loss of visual field (i.e. the solid angle of vision that defines whether an object is within view). Unless checked, the
35 impairment of the visual field leads to absolute and irreversible blindness.

Glaucomas are characterized by a disruption in the normal flow of the "aqueous" (i.e., the clear fluid of the eye having a

composition similar to that of plasma) through the posterior and anterior chambers of the eye (Vaughan, D. *et al.*, In: *General Ophthalmology*, Appleton & Lange, Norwalk, CT, pp. 213-230 (1992)). The aqueous is produced by the ciliary processes and
5 secreted into the posterior ocular chamber. In normal eyes, it then passes through the pupil and into the anterior chamber of the eye. The aqueous flows out of the anterior chamber into a collagen-elastin filtering structure known as the "trabecular meshwork," and ultimately through the "canal of Schlemm"
10 into the venous blood supply. The ability of aqueous to traverse the canal of Schlemm depends upon the presence and extent of transcellular channels and the rate of outflow determines the intra-ocular pressure. The average pressure in normal eyes is about 14 mm Hg. In glaucoma, the outflow of aqueous is
15 disrupted, and intra-ocular pressure increases. Damage usually begins at about 30 mm Hg, and the eye ruptures at about 240 times average pressure values.

The antimitotic agent, 5-fluorouracil, has been proposed as a therapeutic for glaucoma (Sarfarazi, F., U.S. Patent No.
20 5,304,561). Unfortunately, 5-fluorouracil is associated with significant adverse side effects. Since the agents of the present invention can prevent cellular proliferation, they may be used to inhibit the proliferation of the cells of the trabecular meshwork, and accordingly provide a therapy for
25 glaucoma, especially, primary open angle glaucoma. For such uses, it is desirable to employ SDI-1 molecules that can be administered by intra-ocular means (such as by eye drops, or ointments). The ability of a drug to traverse the cornea is enhanced if the drug has both lipophilic and hydrophilic regions.
30 Thus, for intra-ocular delivery, it is desirable to modify the SDI-1 molecules of the invention such that they contain such regions. Suitable lipophilic and hydrophilic groups are known in the art (see, Remington's Pharmaceutical Sciences), and comprise aliphatic groups, lipids, etc. (lipophilic groups) and
35 organic acids, esters, ionic groups, etc. (hydrophilic groups). Such groups can be readily added to the SDI-1 molecules of the present invention by, for example, derivatizing the side chain groups of appropriate amino acids.

Cysteiny residues may be reacted with α -haloacetates (and corresponding amines), such as chloroacetic acid or chloroacetamide, to give carboxymethyl or carboxyamidomethyl derivatives. Cysteiny residues also are derivatized by
5 reaction with bromotrifluoroacetone, α -bromo- β -(5-imidozoyl)propionic acid, chloroacetyl phosphate, N-alkyl-maleimides, 3-nitro-2-pyridyl disulfide, methyl 2-pyridyl disulfide, p-chloromercuribenzoate, 2-chloromercuri-4-nitro-phenol, or chloro-7-nitrobenzo-2-oxa-1,3-diazole.

10 Histidyl residues may be derivatized by reaction with diethylprocarbonate at pH 5.5-7.0 because this agent is relatively specific for the histidyl side chain. Para-bromophenacyl bromide also is useful; the reaction is preferably performed in 0.1 M sodium cacodylate at pH 6.0.

15 Lysiny and amino terminal residues may be reacted with succinic or other carboxylic acid anhydrides. Derivatization with these agents has the effect of reversing the charge of the lysiny residues. Other suitable reagents for derivatizing α -amino-containing residues include imidoesters such as methyl
20 picolinimide; pyridoxal phosphate; pyridoxal; chloroborohydride; trinitrobenzenesulfonic acid; O-methyl-issurea; 2,4 pentanedione; and transaminase-catalyzed reaction with glyoxylate.

Arginy residues may be modified by reaction with one or
25 several conventional reagents, among them phenylglyoxal, 2,3-butanedione, 1,2-cyclohexanedione, and ninhydrin. Derivatization of arginine residues requires that the reaction be performed in alkaline conditions because of the high pK_a of the guanidine functional group. Furthermore, these reagents
30 may react with the groups of lysine as well as the arginine epsilon-amino group.

Carboxyl side groups (aspartyl or glutamyl) may be selectively modified by reaction with carbodiimides ($R^1-N-C-N-R^2$) such as 1-cyclohexyl-3-(2-morpholinyl)-(4-ethyl)
35 carbodiimide or 1-ethyl-3-(4-azonia 4,4-dimethylpentyl) carbodiimide. Furthermore, aspartyl and glutamyl residues may be converted to asparaginy and glutaminy residues by reaction with ammonium ions.

2. Antiviral and Antimicrobial Uses

In an alternative embodiment, the molecules of the present invention may be used as an anti-viral agent to impair the propagation of viruses such as influenza, hepatitis, (e.g., hepatitis B or hepatitis C), Epstein-Barr, rhinovirus, papillomavirus, papovavirus, etc. In particular, since SDI molecules (especially, SDI-1 and its analogs) act to inhibit cellular proliferation, and since retroviruses preferentially proliferate only in actively dividing cells, the present invention provides an antiviral therapy against HIV, and thus can be used to treat diseases such as AIDS and ARC. Similarly, for conditions such as warts (including venereal warts), laryngeal papillomatosis, progressive multifocal leukoencephalopathy, etc., the administration of such SDI molecules inhibits the proliferation of infected cells, and thus provides symptomatic treatment for the condition.

In another embodiment, the molecules of the present invention may be used as an anti-parasitic agent to treat fungal, yeast, protozoan, helminthic, nematodal and other parasitic infections (e.g., candidiasis, aspergillosis, coccidiomycosis, leishmaniasis, amoebiasis, trichomoniasis, tinea (pedis, cruris, etc.) vaginal monolysis, schistosomiasis and malaria).

In a manner similar to that described above, the administration of SDI-1 molecules can increase the therapeutic efficacy of antiviral or antimicrobial agents. Because SDI-1 molecules inhibit the replication of pathogens, it may be applied topically to skin, or systemically via injection, in order to prevent or attenuate the risk of subsequent infection. Thus, for example, the molecules could be incorporated into a suitable pharmaceutical composition, and applied topically to the hands of surgeons or other medical practitioners prior to their exposure to potentially infected individuals.

In another embodiment, the SDI-1 molecules could be administered as an adjunct to antiviral agents in the treatment of suspected or actual viral infection in order to synchronize the cell cycles of any virally infected cells, and thereby enhance the therapeutic efficacy of the antiviral agent.

Likewise, the SDI-1 molecules could be administered as an adjunct to antiparasitic agents in the treatment of suspected or actual parasitic infection in order to synchronize the cell cycles of the cells of the parasite, and thereby enhance the therapeutic efficacy of the antiparasitic agent. Such adjunct administration may be used to treat conditions such as the above-described fungal, yeast, protozoan, helminthic, nematodal or other parasitic infections.

3. Other Therapeutic Uses

The antisense and other SDI inhibitor molecules of the present invention may be used to stimulate the proliferation of spermatocytes, or the maturation of oocytes in humans or animals, and thus, may be used to increase the fertility of a recipient. Conversely, SDI molecules and their analogs can be used to inhibit gametogenesis in males or females, and thus can be used as contraceptive agents to induce infertility in males or females. Such use also provides the benefit of attenuating the replication and proliferation of virally (e.g., HIV, etc.) infected cells, and hence serves to lessen the probability of contracting viral diseases (e.g., AIDS, etc.).

Since the SDI-1 molecules of the present invention are capable of inhibiting DNA replication, they may be used to prevent or attenuate UV-light induced DNA damage (such as that encountered from overexposure to the sun). In individuals who lack normal capacity to repair such damage, the SDI-1-mediated inhibition of DNA synthesis would provide greater opportunity for repair to occur. Hence, the SDI-1 molecules of the present invention may be used to treat individuals suffering from deficiencies in DNA repair capacity (e.g., individuals having xeroderma pigmentosum, ataxia telangiectasia, etc.).

Since the antisense and other inhibitor molecules of the present invention are capable of stimulating cellular proliferation, they may be used to promote wound healing, angiogenesis, endothelial cell proliferation, recovery from burns, or after surgery, or to restore atrophied tissue, etc. The antibodies of the present invention may also be used to effect wound healing, burn recovery, or subsequent to trauma or

surgery. Indeed, all such compounds can also be used to suppress general tissue regeneration or vascularization. For such an embodiment, these agents may be formulated with antibiotics, anti-fungal agents, or the like, for topical or
5 systemic administration.

The molecules of the present invention may be used to provide gene therapy for recipient patients. In one embodiment, cells or tissue from a patient may be removed from the patient and treated with a molecule of the present invention under
10 conditions sufficient to permit a restoration of an active growing state. In one preferred embodiment of this use, lymphocytes of an individual (such as, for example, an immune compromised individual, such as an AIDS patient, etc., or an immune-competent individual who will serve as a donor of
15 lymphocytes) can be removed and treated with antisense SDI nucleic acids. The administration of these molecules will derepress the lymphocytes. After administration, the lymphocytes are reintroduced into the patient, and have an enhanced ability to combat infection.

In yet another embodiment of the present invention, the molecules of the present invention can be used to facilitate autologous cell replacement. In this embodiment, the SDI nucleic acid molecules, their fragments, encoded proteins and polypeptides, and analogs can be used to permit the *in vitro*
20 proliferation of cells (such as bone marrow cells, epithelial cells, muscle cells, hepatic cells, etc.) in order to replenish or augment the amount or concentration of such cells in a patient. Thus, for example, bone marrow cells can be removed, treated with such molecules, and then cultured *in vitro* until a
25 sufficient mass of cells has been obtained to augment a desired immune response. Alternatively, hepatic cells (such as hepatic cells that are free of a hepatitis virus) can be removed from a patient, treated, cultured and then transplanted back into the patient in order to treat hepatic disease.

In one sub-embodiment, such treated cells may be themselves directly transplanted back into the patient, and thus propagate *in vivo*. Alternatively, as indicated, such cells
35

may be cultured *in vitro*, and reintroduced when a desired titer has been attained.

5 In accordance with the above-described embodiments and sub-embodiments of gene therapy, the SDI-1 cDNA and antisense sequences may be operably linked to tumor-specific or tissue-specific promoters in order to confine the therapeutic effect to a desired site or tissue. Examples of suitable tumor-specific promoters include those that direct the transcription of tumor specific antigens such as α -fetoprotein, carcinoembryonic antigen, amylase, γ -glutamyl transferase, etc. Examples of suitable tissue-specific promoters include the phenylalanine hydroxylase promoter (Wang, Y. *et al.*, *J. Biol. Chem.* 269:9137-9146 (1994); Svensson, E. *et al.*, *Eur. J. Hum. Genet.* 1:306-313 (1993); Konencki, D.S. *et al.*, *Biochemistry* 31:8363-8368 (1992)), the alpha-1-antitrypsin (AAT) promoter (Li, Y. *et al.*, *Molec. Cell. Biol.* 8:4362-4369 (1988); the muscle actin promoter, etc. Of particular interest are promoters that direct expression in breast, liver, lung or colon tissues.

20 The molecules of the present invention are particularly suitable for use in the creation and/or study of animal models for disease or tissue degeneration. Thus, the molecules of the present invention can be used to study effectors of an animal model that is characterized by abnormal aging or cellular degeneration. Similarly, the administration of the SDI molecules (linked, for example to suitable regulatory sequences in order to permit their expression in a recipient cell) can be used to create animal models of aging or of tissue degeneration.

30 D. Delivery of Pharmacological Agents

The capacity of SDI-1 to directly enter a cell provides a means for accomplishing the delivery of pharmacological agents to a recipient cell. Thus, in one embodiment, a pharmacological agent will be conjugated to SDI-1 and provided to a recipient patient. The presence of the SDI-1 moiety (which may be the intact SDI-1 protein, or a transport-sufficient

fragment of SDI-1) transports the attached pharmacological agent into the recipient cell.

Any of a variety of cross-linking agents may be used to conjugate the pharmacological agent to the SDI-1 moiety.

5 Alternatively, such agents can be provided as fusion proteins (exemplified by the above-discussed GST-SDI-1 fusion proteins). Such fusion proteins can be prepared by, for example, expressing a nucleic acid molecule that encodes such a fusion.

10 The pharmacological agents that may be administered to cells in this manner may include agents that provide a therapeutic benefit to cells (such as an antihypertensive, anti-inflammatory, anti-arrhythmic, etc.). Alternatively, the pharmacological agent may adversely affect recipient cells
15 (such as by comprising a cytokine, a toxin, etc.).

Where it is desired that the pharmacological agents to be delivered is SDI-1, such can be accomplished using the anti-SDI antibodies of the present invention may comprise chimeric binding regions. By selecting the binding portions of such
20 chimeric antibodies to include a binding domain that is specific for a tumor antigen, it is possible to produce an antibody that can bind to both a tumor antigen and to an SDI molecule. Such a molecule can be used to "ferry" an SDI protein into any cell that arrays the tumor antigen. The conveyed SDI molecule can
25 induce the tumor cell to resume a quiescent or senescent state. Such chimeric antibodies thus comprise an anti-cancer treatment.

Alternatively, the SDI molecules of the present invention may be provided to cells by fusing the SDI molecule to a
30 hormone, or other molecule that can bind to a desired subset of recipient cells. Thus, for example by conjugating SDI-1 to a soluble CD4 molecule, or to an insulin molecule, one could target the administration of SDI-1 to leukocytes that array CD4, or to cells that array the insulin receptor. Although such conjugates
35 can be produced using a variety of methods, it is preferred to produce such conjugates by expressing nucleic acid molecules that encode the fusion proteins.

As indicated, a GST-SDI fusion is a particularly preferred fusion. The N-terminal domain of rat GST exhibits significant homology to human migration inhibition factor (MIF) (David, J.R., *Parasitology Today* 9:315-316 (1993); Mikayama, T. *et al.*, *Proc. Natl. Acad. Sci. (U.S.A.)* 90:10056-10060 (1993), herein incorporated by reference). Thus, distinct from any action of SDI, GST thus has the potential for binding to cellular receptor that are capable of binding MIF and related molecules. Indeed, one aspect of the present invention involves the recognition that a GST-pharmacological agent fusion protein can bind to cellular receptors and effect the delivery of the pharmacological agent to the target cell. Thus, molecules other than SDI could be fused to GST sequences (such as those described above) in order to effect their delivery into a desired target cell.

E. Preparatory Uses

The anti-SDI antibodies of the present invention provide a facile means for purifying and recovering SDI protein from solution. In this embodiment, cellular lysates or extracts are incubated in the presence of an anti-SDI antibody, preferably immobilized to a solid support. The SDI molecules bind to the antibody, and can thus be recovered in purified form.

F. Uses of the SDI Cellular Receptor and Its Solubilized Derivatives

The SDI cellular receptor and its solubilized derivatives can be used to facilitate the recovery of SDI from SDI protein-containing preparations. In this manner, the receptor may be used as a pseudo-antibody. The receptor may also be used therapeutically to modulate cellular expression and responses to SDI protein. Thus, receptor molecules can be provided to tumor cells (via liposomes, or by providing such cells with nucleic acid that encodes the receptor). Such molecules will increase the capacity of the tumor cells to respond to SDI presence, and will thereby ameliorate the cancer.

V. Methods of Administration

The SDI molecules of the present invention can be formulated according to known methods to prepare pharmaceutically useful compositions, whereby these materials, or their functional derivatives, having the desired degree of purity are combined in admixture with a physiologically acceptable carrier, excipient, or stabilizer. Such materials are non-toxic to recipients at the dosages and concentrations employed. The "SDI molecule" of such compositions may be SDI-1 protein, fusions (e.g., GST-fusions, etc.) or fragments of SDI-1 protein or mimetics of such molecules. The SDI molecules may be sense, antisense or triplex oligonucleotides of the SDI-1 cDNA or gene. A composition is said to be "pharmacologically acceptable" if its administration can be tolerated by a recipient patient. Such an agent is said to be administered in a "therapeutically effective amount" if the amount administered is physiologically significant. An agent is physiologically significant if its presence results in a detectable change in the physiology of a recipient patient.

Suitable vehicles and their formulation, inclusive of other human proteins, e.g., human serum albumin, are described, for example, in Remington's Pharmaceutical Sciences (16th ed., Osol, A., Ed., Mack, Easton PA (1980)). In order to form a pharmaceutically acceptable composition suitable for storage or administration, such compositions will contain an effective amount of one or more "SDI molecule."

If the composition is to be water soluble, it may be formulated in a buffer such as phosphate or other organic acid salt preferably at a pH of about 7 to 8. If the composition is only partially soluble in water, it may be prepared as a microemulsion by formulating it with a nonionic surfactant such as Tween, Pluronics, or PEG, e.g., Tween 80, in an amount of, for example, 0.04-0.05% (w/v), to increase its solubility. The term "water soluble" as applied to the polysaccharides and polyethylene glycols is meant to include colloidal solutions and dispersions. In general, the solubility of the cellulose derivatives is determined by the degree of substitution of ether

groups, and the stabilizing derivatives useful herein should have a sufficient quantity of such ether groups per anhydroglucose unit in the cellulose chain to render the derivatives water soluble. A degree of ether substitution of at least 0.35 ether groups per anhydroglucose unit is generally sufficient. Additionally, the cellulose derivatives may be in the form of alkali metal salts, for example, the Li, Na, K, or Cs salts.

Optionally other ingredients may be added such as antioxidants, e.g., ascorbic acid; low molecular weight (less than about ten residues) polypeptides, e.g., polyarginine or tripeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids, such as glycine, glutamic acid, aspartic acid, or arginine; monosaccharides, disaccharides, and other carbohydrates including cellulose or its derivatives, glucose, mannose, or dextrans; chelating agents such as EDTA; and sugar alcohols such as mannitol or sorbitol.

Additional pharmaceutical methods may be employed to control the duration of action. Controlled or sustained release preparations may be achieved through the use of polymers to complex or absorb the SDI molecule(s) of the composition. The controlled delivery may be exercised by selecting appropriate macromolecules (for example polyesters, polyamino acids, polyvinyl pyrrolidone, ethylenevinylacetate, methylcellulose, carboxymethylcellulose, or protamine, sulfate) and the concentration of macromolecules as well as the methods of incorporation in order to control release.

Sustained release formulations may also be prepared, and include the formation of microcapsular particles and implantable articles. For preparing sustained-release compositions, the SDI molecule(s) of the composition is preferably incorporated into a biodegradable matrix or microcapsule. A suitable material for this purpose is a polylactide, although other polymers of poly-(α -hydroxycarboxylic acids), such as poly-D-(-)-3-hydroxybutyric acid (EP 133,988A), can be used. Other biodegradable polymers include poly(lactones), poly(orthoesters), polyamino acids,

hydrogels, or poly(orthocarbonates) poly(acetals). The polymeric material may also comprise polyesters, poly(lactic acid) or ethylene vinylacetate copolymers. For examples of sustained release compositions, see U.S. Patent No. 3,773,919, 5 EP 58,481A, U.S. Patent No. 3,887,699, EP 158,277A, Canadian Patent No. 1176565, U. Sidman et al., "Biopolymers" 22:547 [1983], and R. Langer et al, "Chem. Tech." 12:98 [1982].

Alternatively, instead of incorporating the SDI molecule(s) of the composition into polymeric particles, it is 10 possible to entrap these materials in microcapsules prepared, for example, by coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatine-microcapsules and poly(methylmethacrylate) microcapsules, respectively, or in colloidal drug delivery 15 systems, for example, liposomes, albumin microspheres, microemulsions, nanoparticles, and nanocapsules or in macroemulsions. Such techniques are disclosed in Remington's Pharmaceutical Sciences (1980).

In one embodiment, such formulations will contain an 20 SDI-1 molecule (e.g., a GST-SDI-1 fusion, etc.) that can mediate its own intracellular uptake. Suitable methods are known in the art, see, for example, for example, by Biessen, E.A.L. et al. (PCT Application WO94/04545), Felgner, P.L. (PCT Patent Application WO91/17424), Akiyama, K. et al. (PCT Application 25 WO93/20801), Blum, A. et al. (PCT Application WO93/04672), Abai, A.M. et al. (PCT Application WO93/03709), Hosokawa, S. et al. (U.S. Patent No. 5,264,221), Cullis, P.R. et al. (U.S. Patent No. 5,204,112; U.S. Patent No. 5,252,263), Japanese Patent No. 4,082,893, Phillips, W.T. et al. (U.S. Patent No. 5,158,760), 30 Weiner, N.D. (PCT Application WO91/01719), Hostetler, K.Y. et al. (U.S. Patent No. 5,223,263), Kobayashi, Y. et al. (European Patent 335597); Weiner, A.L. et al. (PCT Application WO89/05151); Hope, M.J. et al. (PCT Application WO87/07530), all herein incorporated by reference.

35 In a second embodiment, liposome formulations and methods that permit intracellular uptake of the SDI-1 molecule will be employed. Suitable methods are known in the art, see, for example, Chiczy, R.M. et al. (PCT Application WO 94/04557),

Jaysena, S.D. *et al.* (PCT Application WO93/12234), Yarosh, D.B. (U.S. Patent No. 5,190,762), Callahan, M.V. *et al.* (U.S. Patent No. 5,270,052) and Gonzalezro, R.J. (PCT Application 91/05771), all herein incorporated by reference.

5 The SDI pharmaceutical compositions used for therapeutic administration may be sterilized, as by filtration through sterile filtration membranes (e.g., 0.2 micron membranes). The compositions may be stored in lyophilized form or as a liquid solution. It will be understood that use of
10 certain of the foregoing excipients, carriers, or stabilizers will result in the formation of salts of the SDI molecules.

 The compositions of the present invention can be applied topically as to the skin, or to gastrointestinal, vaginal, oral, etc. mucosa. When applied topically, the SDI molecule(s) of the
15 composition may be suitably combined with other ingredients, such as carriers and/or adjuvants. There are no limitations on the nature of such other ingredients, except that they must be pharmaceutically acceptable and efficacious for their intended administration, and cannot degrade the activity of the active
20 ingredients of the composition. Examples of suitable vehicles include ointments, creams, gels, or suspensions, with or without purified collagen. The compositions also may be impregnated into transdermal patches, plasters, and bandages, preferably in liquid or semi-liquid form.

25 For obtaining a gel formulation, the SDI molecule(s) of the composition formulated in a liquid composition may be mixed with an effective amount of a water-soluble polysaccharide or synthetic polymer such as polyethylene glycol to form a gel of the proper viscosity to be applied
30 topically. The polysaccharide that may be used includes, for example, cellulose derivatives such as etherified cellulose derivatives, including alkyl celluloses, hydroxyalkyl celluloses, and alkylhydroxyalkyl celluloses, for example, methylcellulose, hydroxyethyl cellulose, carboxymethyl cellulose, hydroxypropyl
35 methylcellulose, and hydroxypropyl cellulose; starch and fractionated starch; agar; alginic acid and alginates; gum arabic; pullullan; agarose; carrageenan; dextrans; dextrans; fructans; inulin; mannans; xylans; arabinans; chitosans;

glycogens; glucans; and synthetic biopolymers; as well as gums such as xanthan gum; guar gum; locust bean gum; gum arabic; tragacanth gum; and karaya gum; and derivatives and mixtures thereof. The preferred gelling agent herein is one that is inert to biological systems, nontoxic, simple to prepare, and not too runny or viscous, and will not destabilize the SDI molecule(s) held within it. Preferably the polysaccharide is an etherified cellulose derivative, more preferably one that is well defined, purified, and listed in USP, e.g., methylcellulose and the hydroxyalkyl cellulose derivatives, such as hydroxypropyl cellulose, hydroxyethyl cellulose, and hydroxypropyl methylcellulose. Most preferred herein is methylcellulose.

The polyethylene glycol useful for gelling is typically a mixture of low and high molecular weight polyethylene glycols to obtain the proper viscosity. For example, a mixture of a polyethylene glycol of molecular weight 400-600 with one of molecular weight 1500 would be effective for this purpose when mixed in the proper ratio to obtain a paste.

The compositions of the present invention can also be formulated for administration parenterally by injection, rapid infusion, nasopharyngeal absorption (intranasopharyngeally), dermoabsorption, or orally. The compositions may alternatively be administered intramuscularly, or intravenously. Compositions for parenteral administration include sterile aqueous or non-aqueous solutions, suspensions, and emulsions. Examples of non-aqueous solvents are propylene glycol, polyethylene glycol, vegetable oils such as olive oil, and injectable organic esters such as ethyl oleate. Carriers, adjuncts or occlusive dressings can be used to increase tissue permeability and enhance antigen absorption. Liquid dosage forms for oral administration may generally comprise a liposome solution containing the liquid dosage form. Suitable forms for suspending liposomes include emulsions, suspensions, solutions, syrups, and elixirs containing inert diluents commonly used in the art, such as purified water. Besides the inert diluents, such compositions can also include wetting agents, emulsifying and suspending agents, or sweetening, flavoring, coloring or perfuming agents.

If methylcellulose is employed in the gel, preferably it comprises about 2-5%, more preferably about 3%, of the gel and the SDI molecule(s) of the composition is present in an amount of about 300-1000 μ g per ml of gel. The dosage to be employed is dependent upon the factors described above. As a general proposition, the SDI molecule(s) of the composition is formulated and delivered to the target site or tissue at a dosage capable of establishing in the tissue a maximum dose that is efficacious but not unduly toxic.

Generally, the dosage needed to provide an effective amount of the composition will vary depending upon such factors as the recipient's age, condition, sex, and extent of disease, if any, and other variables which can be adjusted by one of ordinary skill in the art.

Effective amounts of the compositions of the invention can vary from 0.01-1,000 mg/ml per dose or application, although lesser or greater amounts can be used.

When SDI-1 nucleic acid molecules are employed (as in antisense or triplex repression), methods of "gene therapy" are employed. The principles of gene therapy are disclosed by Oldham, R.K. (In: *Principles of Biotherapy*, Raven Press, NY, 1987), and similar texts. Disclosures of the methods and uses for gene therapy are provided by Boggs, S.S. (*Int. J. Cell Clon.* 8:80-96 (1990)); Karson, E.M. (*Biol. Reprod.* 42:39-49 (1990)); Ledley, F.D., In: *Biotechnology, A Comprehensive Treatise, volume 7B, Gene Technology*, VCH Publishers, Inc. NY, pp 399-458 (1989)); all of which references are incorporated herein by reference. Such gene therapy can be provided to a recipient in order to treat (i.e. suppress, or attenuate) an existing condition, or to provide a prophylactic gene therapy to individuals who, due to inherited genetic mutations, or somatic cell mutation, carry a predisposition to glaucoma.

Most preferably, viral or retroviral vectors are employed for this purpose. Examples of suitable vectors are discussed by Fletcher, F.A. *et al.* (*J. Exper. Med.* 174:837-845 (1991)), Mäkelä, T.P. *et al.* (*Gene* 118:293-294 (1992)), Porgador, A. *et al.* (*Canc. Res.* 52:3679-3686 (1992)), Yoshimura, K. *et al.* (*Nucl. Acids Res.* 20:3233-3240 (1992)), Lim, B. *et al.* (*Proc. Natl. Acad. Sci.*

(U.S.A.) 86:8892-8896 (1989)), Ohi, S. *et al.* (*Gene* 89:279-282 1990)), and Russel, S.J. *et al.* (*J. Virol.* 66:2821-2828 (1992)).

Having now generally described the invention, the same will be more readily understood through reference to the following examples which are provided by way of illustration, and are not intended to be limiting of the present invention, unless specified.

EXAMPLE 1

CREATION OF THE cDNA LIBRARY

10 A cDNA library was obtained using RNA from normal human neonatal foreskin fibroblasts, such as the cell line HCA2. To do this, the cells were grown in minimal essential medium with either Earle's or Hanks' balanced salt solution supplemented with 10% fetal bovine serum (GIBCO or Hyclone).
15 Cells were cultured, and their in vitro life span was determined, under the conditions disclosed by Smith, J.R., and Braunschweiger, K.I., *J. Cell Physiol.* 98:597-601 (1979), hereby incorporated by reference. Quiescent cells were made by replacing the normal culture medium with culture medium containing 0.5% serum before the cells become confluent. The
20 cells were maintained in low serum culture for up to 3 weeks.

Total cellular RNA was isolated either by the guanidinium thiocyanate/CsCl method (Garger, S.J. *et al.*, *Biochem. Biophys. Res. Commun.* 117:835-842 (1983)) or a guanidinium thiocyanate/phenol method (Chomczynski, P., and Sacchi, N.,
25 *Anal. Biochem.* 162:156-159 (1987), RNAzol B, Biotecx Lab. Inc. TX). Poly A+ RNA was isolated by oligo (dT) cellulose column chromatography (Collaborative Res. MA).

10 µg of the poly A+ RNA derived from senescent cells, as
30 described above, was converted to double-stranded cDNAs by using RNase H⁻/MMLV reverse transcriptase according to the instructions of the supplier (BRL, MAD), and blunt-ended by T4 polymerase treatment. The double-stranded cDNA preparations were size fractionated by agarose gel electrophoresis, and the
35 2-4.5 kb fraction isolated, for insertion into an expression vector.

The expression vector used for this purpose was a 3.4 kb plasmid, designated pcDSR $\alpha\Delta$ (Figure 1). Plasmid pcDSR $\alpha\Delta$ is a derivative of the plasmid pcDSR α 296, which includes the Okayama-Berg SV40 promoter and the LTR from HTLV-1 (Takebe, Y. *et al.*, *Mol. Cell. Biol.* 8:466-472 (1988); provided by Dr. M. Yoshida (Cancer Inst. of Japan)). Plasmid pcDSR $\alpha\Delta$ was formed by removing a 336 base pair (bp) segment of the PstI-KpnI fragment of pcDSR α 296 and replacing it with 28 bp of a PstI-KpnI fragment from pUC19. The resulting plasmid (pcDSR $\alpha\Delta$) was used as a cloning and expression vector.

Plasmid pSV2cat (Gorman, C. *et al.*, *Mol. Cell. Biol.* 2:1044-1051 (1982)) was provided by Dr. Gretchen Darlington (Texas Children's Hospital). The pcD vector (Okayama, H., and Berg, P., *Mol. Cell. Biol.* 3:280-289 (1983)) was provided by Dr. H. Okayama (Osaka University, Japan); the plasmid has the chloramphenicol acetyltransferase ("CAT") gene inserted between the SV40 promoter and SV40 poly A signal. pcDSR $\alpha\Delta$ -cat was constructed from pcDSR $\alpha\Delta$ by the insertion of 0.8 Kb of a HindIII-SmaI digested SRA promoter fragment into HindIII digested pSV0cat via a two step ligation. A very strong promoter was desired in order to allow for efficient expression screening of the cDNA library. From an analysis of several mammalian expression vectors (pSV2cat, pcD-cat and pcDSR $\alpha\Delta$ -cat, transfected into young cells), the SRA promoter was found to drive the expression of the CAT gene at high efficiency in young cycling cells. The relative CAT activities of these plasmids were calculated by normalizing to the amount of protein used for each reaction. The transcriptional efficiency was about 20-fold greater than that of the conventional pSV2 promoter, which utilizes the SV40 early gene promoter.

pCMV β carries the E. coli β -galactosidase gene driven by the human cytomegalovirus immediate early gene promoter (MacGregor, G.R., and Caskey, C.T., *Nucleic Acids Res.* 17:2365 (1989); provided by Dr. Grant MacGregor, Baylor College of Medicine, TX). Plasmid p β 440, which carries 443 bp of the human β -actin sequence (Nakajima-Iijima, S. *et al.*, *Proc. Natl. Acad. Sci.* 82:6133-6137 (1985); provided by Dr. Kozo Makino,

Osaka University, Japan). Plasmid pHcGAP (Tso, J.Y. *et al.*, *Nucleic Acids Res.* 13:2485-2502 (1985)), which carries a full length human glyceraldehyde 3 phosphate dehydrogenase (GAPDH) cDNA, was obtained from the American Type Culture
5 Collection, Rockville, MD.

For cDNA antisense expression, full length cDNA fragments were excised by BamHI digestion from the originally cloned pcDSR $\alpha\Delta$ vector, and re-ligated in the reverse direction.

cDNAs recovered from the agarose gel were directly
10 inserted into a calf intestine alkaline phosphatase treated SmaI site of pcDSR $\alpha\Delta$, and transformed into E. coli MC1061 or DH-1. Ampicillin resistant colonies were picked randomly and plasmid sizes determined. These procedures were repeated until 2-4.5 kb cDNA insertions were achieved in more than 90
15 percent of the plasmids tested. Then each E. coli colony was picked with toothpicks and 5 colonies combined into one cDNA pool. More than 400 cDNA pools were prepared, grown in 96 well microtiter plates and stored in 14% glycerol at -70°C. For
20 DNA isolation, E. coli from each cDNA pool was cultured in 200 ml, and treated by the standard methods of ethidium bromide/CsCl ultracentrifugation (Garger, S.J. *et al.*, *Biochem. Biophys. Res. Commun.* 117:835-842 (1983)) one or two times, followed by dialysis against TE (10 mM Tris pH 8.0, 1 mM EDTA) solution.

25

EXAMPLE 2

DEAE-DEXTRAN MEDIATED TRANSFECTION AND TRANSIENT EXPRESSION SCREENING

Young, cycling fibroblast cells were seeded at a density of 0.9-1.2 X 10⁵ per well in 6 well tissue culture plates or 35
30 mm tissue culture dishes 18 h prior to transfection. Transfection was done as described by Cullen, B.R., In: *Guide to Molecular Cloning Techniques. Methods in Enzymology.*, S.L. Berger and A.R. Kimmel (ed.) Academic Press, pp. 684-704 (1987); herein incorporated by reference with minor
35 modifications as described below.

For each transfection, 100 ng of pCMV β and 400 ng of a cDNA pool were mixed and suspended in 190 μ l of phosphate buffered saline (PBS) solution and 10 μ l of 10 mg/ml of DEAE-

dextran (Pharmacia, MW ~500,000) was added. 400 ng of the cloning vector plasmid, pcDSR $\alpha\Delta$, was used with pCMV β as a control. After washing the cells with PBS once, DNA solutions were added and the cells incubated for up to 45 min at 37°C in a CO₂ incubator. Then 2 ml of cell culture medium with serum, containing 64 μ M chloroquine (Sigma, MO) was added directly and incubated for another 2.5 h. After the chloroquine treatment, the transfection mixture was removed and the cells treated with 10% dimethyl sulfoxide in cell culture medium with serum for 2 min. Cells were then returned to fresh cell culture medium with serum and incubated to allow for expression of the transfected DNA.

18 h after transfection, 0.5 μ Ci/ ml of ³H-thymidine was added and the incubation continued for another 48 h. Cells were fixed by adding 25 μ l of 25% of glutaraldehyde solution to the culture medium and incubated for 5 min at room temperature, followed by three washings with PBS. Immediately after washing, cells were treated with the X-gal reaction mixture (1 mM MgCl₂, 3 mM K₄[Fe(CN)₆], 3 mM K₃[Fe(CN)₆], 0.1% triton X-100, and 1 mM X-gal dissolved in 0.1 M sodium phosphate buffer (pH 7.5) containing 10 mM KCl) for up to 20 min to allow light-blue staining of the cells. After the X-gal staining, the cells were washed with water, dried and processed for autoradiography using Kodak NTB nuclear track emulsion (Kodak, NY). DNA synthesis activity in X-gal positive cells was then determined. The percent inhibition of DNA synthesis was calculated using the formula:

$$\frac{\left[\begin{array}{l} \% \text{ labeled nuclei in} \\ \text{blue cells in which} \\ \text{control plasmids} \\ \text{were transfected} \end{array} \right] - \left[\begin{array}{l} \% \text{ labeled nuclei in} \\ \text{blue cells in which} \\ \text{cDNA plasmids} \\ \text{were transfected} \end{array} \right]}{\left[\begin{array}{l} \% \text{ labeled nuclei in blue cells in which} \\ \text{control plasmids were transfected} \end{array} \right]} \times 100$$

30

Candidate cDNA pools were divided into individual cDNAs and screened further for the identification of specific DNA synthesis inhibitory cDNA sequences.

Nuclear microinjection of young cycling cells was performed as described by (Lumpkin, C.K. *et al.*, *Mol. Cell Biol.* 6:2990-2993 (1986), herein incorporated by reference). Briefly, 5,000 - 10,000 cells were plated onto 22 mm square etched grid coverslips (Bellco) in 35 mm tissue culture dishes. Three or four days later, nuclear microinjections were performed on a minimum of 300 cells, using either pCMV β + cDNA plasmid or pCMV β + pcDSR $\alpha\Delta$ (which served as the control). Plasmids were co-microinjected at a concentration of 50 ng/ μ l each. 18 hours after microinjection, the cells were labeled with 3 H-thymidine for 24 h, fixed, stained with X-gal and processed for autoradiography. The percent inhibition of DNA synthesis was calculated as above.

Northern blot analysis was performed using either 5 μ g of total RNA or 1 μ g poly A+ RNA. The RNA was size fractionated by electrophoresis on formaldehyde-agarose gels and transferred to nylon membranes (ICN; Biotrans, formerly Pall Biodyne A) as described by Maniatis, T. *et al.*, *Molecular cloning: A Laboratory Manual*; Cold Spring Harbor Laboratory, Cold Spring Harbor, New York (1982), herein incorporated by reference. Radioactive probes were prepared by the random primer method, and blots hybridized as described by Maniatis, T. *et al.*, *Molecular cloning: A Laboratory Manual*; Cold Spring Harbor Laboratory, Cold Spring Harbor, New York (1982).

The northern blot analyses revealed that the sizes of the cellular transcripts of the SDIs were compatible with the sizes of the SDI cDNAs. This was expected since successful expression screening requires full-length cDNA insertions into the vector.

For rehybridization with β -actin or glyceraldehyde phosphate dehydrogenase (GAPDH) probe, filters were repeatedly stripped of the labelled probes following the manufacturer's instructions. The data were quantitated by an Ambis Radioanalytic Scanning System.

An assay of CAT activity was determined as follows: Young cycling cells were seeded into 35 mm dishes and 500 ng of plasmid transfected as described above. 24 hours after the transfection, the cells were scraped from the dish, and CAT

assay performed as described by Gorman (Gorman, C., In: DNA Cloning, A Practical Approach. IRL Press, Oxford, England, pp. 143-164 (1985), herein incorporated by reference).

5

EXAMPLE 3**cDNA CLONING OF THE SENESCENT CELL DERIVED INHIBITORS
(SDI) OF DNA SYNTHESIS**

Double-stranded cDNAs were synthesized from senescent cell derived poly A+ RNA, which has been shown to inhibit DNA synthesis in young cells when microinjected into the cytoplasm (Lumpkin, C.K. *et al.*, *Science* 232:393-395 (1986)). The cDNAs were size fractionated, inserted into pcDSR $\alpha\Delta$. The resulting E. coli clones were divided into small pools. Plasmids from each pool were co-transfected with the transfection marker plasmid, pCMV β , which allowed a determination of the labelling index of transfected cells specifically, since even in high efficiency transfection, frequencies varied from experiment to experiment. Transfection frequencies of the marker plasmid ranged from 30-90%. About 200 cDNA pools were screened and four pools remained positive for DNA synthesis inhibitory activity after five repeated transfections. The candidate pools were then divided into individual plasmids and screened further.

Three independent positive plasmid clones were obtained. In the cDNA pool A, only one plasmid, No. 2, exhibited strong DNA synthesis inhibitory activity. Similarly, in pools B and C only one cDNA clone caused inhibition. The size of inserted cDNAs was 2.1 kb, 1.2 kb and 2.7 kb, respectively. These cDNA sequences have been designated as senescent cell derived inhibitors, SDI-1, SDI-2 and SDI-3, respectively.

The nucleotide sequence of the SDI-1 cDNA clone (SEQ ID NO: 1), and the amino acid sequence of SDI-1 (SEQ ID NO: 2) have been determined. The cDNA sequence presented herein for SDI-1 differs from that described in U.S. Patent Application serial no. 07/808,523 in possessing an unrecited G at position 286, and in having the sequence CG rather than GC at position 1843-1844. The presently disclosed sequence was obtained through the re-sequencing of the pcDSR $\alpha\Delta$ -SDI-1 plasmid whose

isolation and characteristics were described in U.S. Patent Application serial no. 07/808,523. *E. coli* DH5 transformed with the pcDSR $\alpha\Delta$ -SDI-1 plasmid was deposited with the American Type Culture Collection, Rockville, Maryland, USA, on
5 October 1, 1992, and has been accorded accession number ATCC 69081.

A nucleic acid molecule whose sequence corresponds to a portion of the SDI-1 nucleotide sequence reported herein has been identified among the 2375 random gene sequence
10 fragments reported by Adams, M.D. *et al.* (*Nature* 355:632-634 (1992)).

EXAMPLE 4

MICROINJECTION OF SDI SEQUENCES INTO YOUNG CYCLING CELLS

In order to verify the functional activity of SDI
15 sequences, microinjections were performed. A plasmid carrying either SDI-1 or SDI-2 was co-microinjected with the marker plasmid into the nuclei of young cycling cells. The labelling index of the resulting blue cells was determined (Table 1). These plasmids showed strong inhibitory activity on
20 DNA synthesis of young cells. For control experiments, the empty vector was co-microinjected with the marker plasmid. This caused slight inhibition when the labelling index was compared with uninjected cells, a phenomenon also observed in transfection experiments. Microinjections with SDI-3 were not
25 performed because the inhibitory activity was lower than SD-1 and SD-2 transfection experiments.

In addition to normal human fibroblasts, the SDI-1 molecules were also found to be capable of inhibiting the synthesis of DNA in several tumor cell types (melanoma, lung carcinoma, and ovarian tumor), and in immortalized SV40-
30 transformed fibroblasts, and CHO cells. SDI-1 molecules were also capable of inhibiting the synthesis of DNA in normal bovine pulmonary artery smooth muscle.

Table 1					
	Plasmids Injected	No. of Cells Injected	No. of Labelled Nuclei per Total Blue Cells*	Labelling Index (%)	% Inhibition
Exp. 1	pCMV β + pcDSR $\alpha\Delta$ †	335	58/97	59.8	0
	pCMV β + SDI-1	380	20/89	22.5	62.4
	pCMV β + SDI-2	380	6/82	7.3	87.8
Exp. 2	pCMV β +pcDSR $\alpha\Delta$ †	423	68/109	62.3	0
	pCMV β + SDI-1	465	26/98	26.5	57.5
	pCMV β + SDI-2	475	27/118	22.9	63.2
Notes: † Control; * The number of cells expressing detectable levels of β -galactosidase; The concentration of each DNA was 50 μ g/ml.					

EXAMPLE 5

ANTISENSE DNA TRANSFECTION

In order to examine whether any inhibitory activities are sequence orientation specific, antisense expression vectors of SDI-1 and SDI-2 sequences were constructed. Since both sequences lacked BamHI sites and since BamHI sites were present at both ends of the cDNA (Figure 1), the sequences were easily excised and religated in the opposite orientation. Transfection of antisense sequences resulted in no inhibition of DNA synthesis in young cells (Figure 3). In addition, no enhancement was observed. The results clearly indicate the sequence orientation specificity of the SDI activity, and

suggest the presence of specific gene products coded by the cDNA sequences.

Normal human fibroblasts and many other cells cease to synthesize DNA in the absence of appropriate growth factors. Since SDI-1 is a key negative regulator of initiation of DNA synthesis, molecules that are antisense to SDI-1 are able to cause cells to enter S phase. To demonstrate this ability, several normal human cell lines were isolated and provided with SDI-1 antisense molecules (expressed by cloning the SDI-1 cDNA in and antisense orientation into a vector having a metallothionein promoter).

For this purpose, antisense expression vectors were constructed by cloning SDI-1 antisense sequences into PMET, an inducible expression vector containing an altered human metallothioneine promoter. The metallothioneine promoter in PMET was derived from pM26 and contains a deletion in the basal promoter and the addition of synthetic metal response elements in triplicate (McNeall, J. *et al.*, *Gene* 76:81-88 (1989)). For construction of PMET, adenovirus sequences containing E1A gene 12S and 13S introns (nucleotides 917-1673) were first cloned into the mammalian expression vector PRC/CMV (Invitrogen) at the Not I/Apa I sites of the multiple cloning region of this plasmid to create pRc/CMV-Ad. To ensure that no translation of E1A sequences occurred and to create an Spe I cloning site in this vector, an SpeI linker containing a stop codon was inserted between the CMV promoter and E1A splice sequence in-frame with the E1A sequence. The CMV promoter of plasmid Rc/CMV-Ad was then replaced with the pM26 promoter to create PMET. To accomplish this, the metallothioneine promoter was excised from pM26 by BglII digestion and inserted into the BamHI site of pBlueScript (pBS; Stratagene). An EcoRV and NotI fragment containing the promoter was then subcloned from pBS into a filled-in BglII site and NotI site of Rc/CMV-Ad. Antisense sequences from the SDI-1 CDNA were derived from the full-length CDNA cloned into the BamHI site of pBS. The StuI site at nucleotide 127 was converted to an SpeI site by insertion of an SpeI linker to make SDISPE127. An SpeI linker was also

inserted at the Apal site at nucleotide 318 to create SDISPE318. These constructs were digested with SpeI and inserted in antisense orientation into the SpeI cloning site of PMET, thus creating pMET-AS127 and pMET-AS318.

5 Cell lines expressing SDI-1 antisense were obtained by calcium phosphate transfection using the BES/CaPO₄ procedure described by Chen, C. *et al.*, *Molec. Cell. Biol.* 7:2745-2752 (1987)) except that the cells were not replated after transfection. HCA2 cells (3×10^5) at PD10 were transfected
10 with 20 µg PMET, pMETAS127 or pMETAS318 DNA. Following two weeks of G418 selection, colonies were picked and expanded. Inducibility and integrity of the inserted sequence was examined by the addition of 100 µM ZnCl₂ and 2 µM CdCl₂ followed by RNA analysis. RNA analysis of total cell RNA from
15 stable transformants was performed by RNase protection using antisense RNA probes internally labeled with [³²P]-UTP as described by Adami, G. *et al.*, *EMBO J.* 10:3457-3465 (1991)). The probe pMET+SDI-1, containing SDI-1 nucleotides 444-686, was used to measure expression of SDI-1 from both the
20 transfected genes and endogenous mRNA. After EcoNI digestion, transcription from the SP6 promoter in the PMET vector results in a antisense labelled probe that hybridizes to both RNA from the expression expression vector and to endogenous SDI-1 mRNA. This allows a comparison of relative levels of
25 expression from the introduced construct and SDI-1 endogenous RNA. As a control β-actin mRNA was measured in all assays. The actin probe contains nucleotides 2124-2189 inserted between the Eco RI and the filled-in Bam HI sites of pBS.

When the stably transfected cells were placed in medium
30 containing lowered amounts of growth factors (0.5% fetal bovine serum) for 7-10 days and pulse labelled for 24 hours with tritiated thymidine, fewer than 5% incorporated label. However, when antisense SDI-1 was induced by the addition of ZnCl₂ and CdCl₂ 24 hours prior to the addition of the tritiated
35 thymidine, more than 25% of the cells were found, by incorporation of label, to have initiated the synthesis of new DNA, and thus to have regained the capacity to proliferate.

This experiment shows that the antisense sequences of the present invention can be used to immortalize cells that would absent such treatment undergo senescence.

5

EXAMPLE 6**EXPRESSION OF SDI mRNAs DURING CELLULAR SENESCENCE**

To examine the changes in SDI mRNA expression during cellular senescence, total RNA from young and senescent cells was hybridized to ³²P-labelled SDI cDNA probes. The SDI-1 probe hybridized to a 2.1 kb cellular transcript, SDI-2 hybridized to a 1.4 kb transcript, and SDI-3 hybridized to a 2.5 kb transcript (Table 2). Table 2 provides a quantitation of the total RNA northern analysis of expression of SDI genes in young (Y) and senescent (S) cells. 5 µg each of total RNA from young and senescent cells were hybridized with SDI probes. The filters were repeatedly stripped of the radioactive probe and rehybridized with the probes for the internal controls. The relative amount of SDI mRNA in each sample was normalized by the amount of GAPDH detected on the same filter and by the relative amount of SDI/GAPDH.

Table 2: Quantitation of the Northern Analysis						
ATTRIBUTE	SDI-1		SDI-2		SDI-3	
	Y	S	Y	S	Y	S
Relative Amount of SDI	1.0	3.3	1.0	0.31	1.0	0.31
Relative Amount of GAPDH	1.0	0.37	1.0	0.36	1.0	0.38
Relative Amount of SDI / GAPDH	1.0	9.3	1.0	0.86	1.0	0.82

During cellular senescence, the SDI-1 message increased about 3-fold, while SDI-2 and SDI-3 messages decreased 3-fold. The same filters were rehybridized with a β-actin, and then to a GAPDH probe as internal controls. The results demonstrated that expression of both control genes decreased about 3-fold during cellular senescence. In previous studies, a 2-3 fold decrease of β-actin expression during cellular senescence had been observed (Kumazaki, T. *et al.*, *Exp. Cell Res.*

195:13-19 (1991); Seshadri, T., and Campisi, J., *Science* 247:205-209 (1990); Furth, J.J., *J. Gerontol.* 46:B122-124 (1991)). The decreased expression of both β -actin and GAPDH genes in senescent cells led to the use of poly A+ RNA for northern analysis. Poly A+ RNA was isolated from the total cellular RNA preparations used for Table 2, and hybridized to SDI cDNA, followed by probing with β -actin and GAPDH respectively (Table 3). Table 3 discloses the results of a poly A+ RNA Northern analysis of SDI gene expression in young (Y) and senescent (S) cells. 1 μ g each of poly A+ RNA from young and senescent cells were used for the analyses. The relative amount of SDI mRNA in each sample was calculated as in Table 2.

Table 3: Quantitation of the Northern Analysis						
ATTRIBUTE	SDI-1		SDI-2		SDI-3	
	Y	S	Y	S	Y	S
Relative Amount of GAPDH	1.0	0.83	1.0	0.87	1.0	0.87
Relative Amount of SDI / GAPDH	1.0	11.4	1.0	1.0	1.0	1.0

The results clearly indicated that the expression of both β -actin and GAPDH was equal in young and senescent cells when they were compared on the basis of mRNA, consistent with previous observations. When SDI gene expression was compared at the mRNA level, SDI-1 mRNA was increased 11-fold in senescent cells, whereas expression of SDI-2 and SDI-3 remained constant throughout the in vitro lifespan (Table 3). This result suggests that SDI-1 is a senescent cell specific inhibitor of DNA synthesis, whereas SDI-2 and SDI-3 are most likely more general inhibitors involved in cell cycle regulation.

EXAMPLE 7

CHANGES OF POLY A RNA CONTENT DURING CELLULAR SENESENCE

The observation that the results of the total versus poly A+ RNA northern analyses were quantitatively different, indicated that the poly A+ RNA content in total RNA

preparations might change during cellular senescence. To test this hypothesis, cells were cultivated serially and total RNA was harvested at different population doubling levels. Poly A+ RNA was isolated from each sample.

5 The result clearly indicated that poly A+ RNA content decreased gradually during cellular senescence (Figure 4). In Figure 4, cells were cultivated serially and total RNA was harvested. Poly A+ RNA: % of total RNA was plotted against the culture's age (% in vitro life span completed). Senescent cells
10 had 3-4 fold less poly A+ RNA when compared with very young cells. However, when total RNA content per cell was calculated, senescent cells had 1.3-1.5 fold more than young cells (see, Cristofalo, V.J., and Kritchevsky, D., *Med. Exp.* 19:313-320 (1969)).

15 In order to determine whether SDI-1 message increased gradually during subcultivation or whether a rapid increase occurred near the end of the in vitro life span, poly A+ RNA from cultures at different population doublings was hybridized with the ³²P labelled SDI-1 probe. This analysis revealed that
20 SDI-1 expression increased as the cultures became senescent, with a major change occurring during the final few passages (Table 4). Table 4 shows the accumulation of SDI-1 mRNA during cellular aging process. One microgram each of poly A+ RNA from the cells of different population doublings were
25 hybridized to SDI-1 probe. The relative amount of SDI-1 mRNA in each sample was calculated as in Table 2.

Table 4: Quantitation of % Lifespan Completed							
ATTRIBUTE	24%	37%	46%	66%	78%	88%	100%
Relative Amount of GAPDH	1.0	1.6	1.5	1.3	1.4	1.3	0.9
Relative Amount of SDI / GAPDH	1.0	2.2	2.1	4.0	3.5	6.2	20.5

30 Changes in SDI-1 expression during quiescence were also examined. Young, quiescent cells were maintained in 0.5% fetal bovine serum (FBS)-containing medium for up to three weeks. Total RNA was harvested each week and the amount of RNA hybridizing to the SDI-1 probe was analyzed. SDI-1 message

increased significantly during cellular quiescence (Table 5). Table 5 shows the accumulation of SDI-1 mRNA during cellular quiescence. 4 μ g each of total RNA was obtained from the young cells cultured with 0.5% FBS containing medium for 1, 2, 3 weeks, was hybridized with SDI-1 probe. The relative amount of SDI-1 mRNA was calculated as in Table 2 (C: control culture with 10% FBS medium). When the result was normalized to GAPDH expression, SDI-1 expression was found to have increased 18-fold after two weeks in low serum medium compared to that of a control dividing culture in 10% FBS medium.

Table 5: Accumulation of SDI-1 mRNA During Cellular Quiescence				
ATTRIBUTE	C	1 wk	2 wk	3 wk
Relative Amount of GAPDH	1.0	0.72	0.88	0.37
Relative Amount of SDI / GAPDH	1.0	12.2	18.4	14.9

The fact that the cellular representation of mRNA vs total RNA was found to change during cellular senescence is significant. During the in vitro aging process, the content of mRNA was found to decrease gradually (Figure 4), in spite of the slight increase of the total RNA per cell. This phenomenon indicates that a gradual decline of the overall gene expressions during the cellular aging process, and explains the decreased expression of β -actin and GAPDH genes in senescent cells when Northern blot analysis was done with total RNA (Table 2). However, the expression levels of these housekeeping genes between young and senescent cells were almost constant when the Northern blot analysis was done with poly A+ RNAs (Table 3). This analysis revealed the strong expression of SDI-1 message in senescent cells, and unchanging expression of SDI-2 and 3 genes throughout the in vitro life span.

EXAMPLE 8
THE SDI-1 GENE

The SDI-1 gene codes for a senescent cell specific inhibitor of DNA synthesis. Increased expression of this gene occurred when the cells entered their final few divisions (Table 4). The expression kinetics correlated well with the phenotypic expression of senescence cells. SDI-1 gene expression was also found to increase after young cells were made quiescent and nondividing by serum deprivation (Table 5). This result demonstrates the involvement of this gene in the inhibition of DNA synthesis of cellular quiescence as well as senescence. Cells made quiescent by deprivation of serum growth factors have been shown to produce an inhibitor of DNA synthesis with characteristics similar to the inhibitor from senescent cells (Pereira-Smith, O.M. *et al.*, *Exp. Cell Res.* 160:297-306 (1985); Stein, G.H., and Atkins, L., *Proc. Natl. Acad. Sci. USA.* 83:9030-9034 (1986)).

The fact that SDI-1 expression increases during both senescence and quiescence indicates that it is an inhibitor of DNA synthesis (Smith, J.R., *J. Gerontol.* 45:B32-35 (1990); herein incorporated by reference). Alternatively, SDI-1 sequences might be related to the growth arrest-specific genes recently cloned from mouse cells (Schneider, C. *et al.*, *Cell* 54:787-793 (1988); Manfioletti, G. *et al.*, *Mol. Cell. Biol.* 10:2924-2930 (1990)).

EXAMPLE 9
THE EXPRESSION OF THE SDI-1 GENE PRODUCT

SDI-1 cDNA has been expressed in two different bacterial expression systems, has been transcribed in vitro and translated in two different in vitro systems. Two bacterial expression systems were used in order to maximize the probability of obtaining sufficient amounts of SDI-1 protein. In the first expression system, SDI-1 protein was expressed as a glutathione S-transferase fusion protein at yields of 5-10 μ g per liter of bacterial culture. The recombinant protein could be cleaved with thrombin and purified in order to give an SDI-1 protein with a few extra amino acids. The GST fusion was

5 formed by cleaving a *Schistosoma japonicum* GST-encoding polynucleotide with BamHI so as to produce a cleavage fragment that contained nucleotides 1-673 of the GST-coding sequence. The free BamHI site at position 673 generated via such treatment was then ligated to the SDI-1 encoding polynucleotide in order to form the GST-SDI-1 gene fusion. The GST-SDI-1 fusion protein was produced via recombinant expression of this gene fusion.

10 In the second expression system, a 6 histidine amino terminal tag was utilized in order to aid in purification. This recombinant protein may be used without further modification. Both systems permitted the isolation of pure preparations of protein.

15 In the course of this experiment, *in vitro* transcription and translation systems were used to confirm the open reading frame deduced from the nucleic acid sequence of the SDI-1 cDNA. The calculated molecular weight of the SDI-1 protein is approximately 16,000 daltons. The *in vitro* synthesized protein migrates, by SDS PAGE, with a relative mobility of approximately 21,000 daltons. This small difference may be due to a slightly unusual charge or conformation of the SDI-1 protein. A partial amino acid sequence of the bacterially expressed protein verified the open reading frame (SEQ ID NO:2).

25 The bacterially expressed proteins were used to generate polyclonal antisera and monoclonal antibodies to the intact native protein. Such antibodies may be more effective in immunoprecipitation of SDI-1 protein and SDI-1 protein complexes than the antisera produced from synthetic peptides. Preliminary immunocytochemical studies, using an antisera of highest affinity (antisera #55) which reacted strongly with the fusion protein on a western transfer at a 1:20,000 dilution, suggested that the SDI-1 protein was relatively abundant in senescent cells compared to dividing young cells. In senescent cells the location appears to be perinuclear, whereas in young cells there appears to be a small amount of SDI-1 protein located in the nucleus. In order to obtain specific staining it was necessary to pre-absorb the antisera against a fixed cell monolayer of cells which do not express detectable levels of

SDI-1 mRNA (TE85). The cells were fixed with 4% paraformaldehyde followed by methanol.

In order to study the cellular phenotype resulting from the induced expression of SDI-1 mRNA in cells which normally
5 express the gene at low levels and to examine the effect of antisense SDI-1 constructs it is desirable to obtain cell lines in which the SDI-1 gene is stably integrated under the control of an inducible promoter. Toward this goal, a functional vector containing SDI-1 under the control of the metallothionine
10 promoter was constructed. Following transfection of this construct into young proliferation competent cells and incubation in the presence of 100 μ M zinc chloride and 2 μ M cadmium chloride, initiation of DNA synthesis was inhibited by about 50%. In the absence of metals there was no inhibition of
15 DNA synthesis. The inhibitory activity observed is not due to metal toxicity since cells transfected with the control vector (pcDSR α) and grown in the presence of metals were found to have approximately 90% of the DNA synthetic capacity of cells transfected with the same plasmid grown in the absence of
20 metals.

In order to demonstrate that the inhibitory effects observed with SDI-1 were not related to the nature of the specific promoter used to drive expression, the capacity of SDI-1, expressed from other promoters, to inhibit DNA
25 synthesis was investigated. Young proliferating human fibroblasts were therefore co-transfected with CMV- β -gal and CMV-SDI-1. Transfection of cells with CMV- β -gal had little effect on DNA synthesis while CMV-SDI-1 was even more effective than SDI-1 in the pcDSR α vector in these particular
30 experiments.

The SV40 large T antigen is capable of inducing senescent cells to synthesize DNA. It was therefore of interest to determine whether the inhibitory action of SDI-1 could be overcome by the expression of T antigen. Moreover, it was
35 desirable to determine that the action of SDI-1 was not due to the induction of a general metabolic imbalance in cells. If such were the case, one would not expect large T antigen to antagonize its effect. For these reasons, cells were co-

transfected with SDI-1 cDNA and vectors in which T antigen was driven by the CMV promoter. Such co-transfection experiments revealed that the inhibitory activity of SDI-1 was largely abolished by the co-expression of the SV40 large T antigen.

Transient transfection assays were performed using an additional normal human fibroblast cell line (neonatal foreskin cell line (CSC303) and the WI38 immortal cell line in order to determine the generality of the inhibitory effect of SDI-1. In both cases, significant inhibition (40-50%) was observed. Furthermore, SDI-1 was found to inhibit SUSMI (40%) but not an SV40 transformed cell line GM639 or HeLa cells (< 20%). The results thus far are consistent with earlier results obtained from heterokaryon experiments in which HeLa cells and cells transformed with SV40 virus were not inhibited by fusion with senescent cells. This provides further evidence that SDI-1 behaves like the inhibitor previously detected in senescent cells.

20

EXAMPLE 10

SOUTHERN ANALYSIS OF THE SDI-1 GENE

In order to determine whether the absence or inactivity of SDI-1 was responsible for cellular immortality in any of the four complementation groups for indefinite division, genomic DNA and mRNA was examined from cell lines representative of the four groups. Southern analysis revealed the expected 5 and 10 kb bands after digestion with EcoRI. Therefore, no gross deletions or rearrangements have occurred in the SDI-1 gene in these cell lines. By Northern analysis, it was determined that SDI-1 mRNA was lower or absent in the cell lines that had been assigned to complementation groups B and C. SDI-1 was present at higher levels in cell lines representative of complementation groups A and D. This results suggests that part of the mechanism by which the cell lines may have escaped cellular senescence is through the loss of ability to express sufficient levels of the active SDI-1 gene.

EXAMPLE 11
CHARACTERIZATION OF SDI SEQUENCES

Using a functional screening method, a novel DNA synthesis inhibitory gene, SDI-1, was identified. The gene is expressed at high levels in nonproliferating human diploid fibroblasts. Message levels of SDI-1 increased 10 to 20-fold as normal human cell cultures were aged *in vitro*, with the expression kinetics correlating closely with the phenotypic expression of cellular senescence. In addition, SDI-1 message increased when cells were made quiescent by growth factor deprivation.

The results described above demonstrate that SDI-1 codes for a novel, physiologically active gene product that is important for cell cycle control. Expression of the gene is modulated during exit from G₀ and entry into S phase in cells that have been stimulated to enter the cell cycle. In addition, expression of antisense SDI-1 message stimulates cells to enter the cell cycle in the absence of growth factors. The observation that SV40 T antigen can counteract the inhibitory activity of SDI-1 in a manner similar to that observed with the negative growth regulators p53 and Rb (Lane, D.P. *et al.*, *Nature* 278:261-263 (1979); Linzer, D.I.,H. *et al.*, *Cell* 17:43-52 (1979); De Caprio, J.A. *et al.*, *Cell* 54:275-283 (1988)), underscores the importance of this gene product in the regulation of the cell cycle.

The recombinant SDI-1 protein of the present invention inhibits the phosphorylation of histone H1 by CDK2. Since SDI-1 blocks DNA synthesis, this finding indicates that the phosphorylation of histone H1 has a role in the initiation of DNA synthesis.

The SDI-1 gene product is also a potent inhibitor of several cyclin-dependent kinases, including CDC2, CDK2, and CDK4. In similar experiments using human cell extracts, recombinant SDI-1 was found to inhibit CDK2 kinase activity. These results are of particular importance in view of what is known about the various proteins involved in cell cycle progression. Several human G1 cyclin candidates (cyclins C, D, and E), identified by their ability to complement a budding

yeast strain that lacked G1 cyclins (Xiong, Y. *et al.*, *Cell* 65:691-699 (1991); Lew, D.J. *et al.*, *Cell* 65:1197-1206 (1991); Xiong, Y. *et al.*, *Curr. Biol.* 1:362-364 (1991); Koff, A. *et al.*, *Cell* 66:1217-1228 (1991)), were found to be cell cycle regulated, with maximal mRNA expression occurring at different points in G1 (Lew, D.J. *et al.*, *Cell* 65:1197-1206 (1991)). Since D-type cyclins and cyclin E are associated with active kinase complexes (Koff, A. *et al.*, *Cell* 66:1217-1228 (1991); 1992; Dulic, V. *et al.*, *Science* 257:1958-1961 (1992); Matsushime, H. *et al.*, *Cell* 65:701-7139 (1991); Ewen, M.E. *et al.*, *Cell* 73:487-4976 (1993); Kato, J.Y. *et al.*, *Genes Devel.* 7:331-342 (1993), it is likely that these kinases have a role in the commitment of mammalian cells to a new round of cell division at the "restriction point." (Pardee, A.B., *Science* 246:603-608 (1989)). Indeed, recent reports indicate that cyclin E-CDK2 kinase complexes have maximal activity in late G1 and early S phase (Dulic, V. *et al.*, *Science* 257:1958-1961 (1992); Koff, A. *et al.*, *Cell* 66:1217-1228 (1991)), and also have the ability to phosphorylate the RB protein in cultured human cells (Hinds, P.W. *et al.*, *Cell* 70:993-1006 (1992)) and *in vitro* (Ewen, M.E. *et al.*, *Cell* 73:487-4976 (1993)). This suggests that the kinase may play a pivotal role in the regulation of the G1-to-S phase transition of the cell cycle.

Immunoblots of SDI-1 protein have revealed that levels of this protein do not appear to vary extensively in cells in different growth states (ie. actively growing versus quiescent or senescent cells). However, consistently higher amounts of protein are present in non-dividing compared with proliferating cells. This seems reasonable because SDI-1 is a potent negative regulator of CDK activity, and tight regulation of this inhibitor would be essential for proper cell cycle regulation and progression. Small changes in the amount of inhibitor protein could result in a major impact on the various gene products it controls. At least two CDKs: CDC2 and CDK2, maintain relatively constant steady-state protein levels through the cell cycle despite cell cycle phase-dependent changes in mRNA. SDI-1 may be regulated in a similar manner, such that the level of SDI-1 protein is precisely controlled at a

particular level, and that new CDK/cyclin synthesis and activation is needed to overcome the inhibitory effects of SDI-1 to allow for progression through the cell cycle. Thus, SDI-1 would prevent entry into the cell cycle until a required
5 threshold of stimulatory gene products were present, allowing the cell to proceed through the "restriction point" of the cell cycle. Such a dynamic equilibrium between active CDK/cyclin complexes and the inhibitor SDI-1 protein explains the observed stimulation of DNA synthesis in quiescent cells
10 following a small decrease in the steady-state levels of SDI-1 protein due to antisense SDI-1 mRNA expression. Thus, SDI-1 may function in the cell in a manner similar to other cell proliferation inhibitors, such as the tumor suppressor genes p53 and Rb, and the SDI-1 gene may be a target for mutation in
15 various tumors.

Although senescent cells cannot be stimulated to enter S phase by the addition of mitogens, they do express mRNAs for many cell cycle-regulated genes including cyclins D1, cyclin E, CDK2, Rb, p53, c-H-ras, c-myc, c-jun, and jun B. However,
20 several other important cell cycle-regulated genes, including c-fos, histone H3, CDC2, cyclin A, cyclin B1, and PCNA, are not expressed in mitogen-stimulated senescent cells. The lack of phosphorylation of the protein product of the retinoblastoma susceptibility gene Rb in senescent cells could be one cause for
25 the inability of senescent cells to synthesize DNA. However, cyclin E-CDK2 complexes, though relatively abundant in senescent cells, lack the kinase activity which could potentially phosphorylate Rb in vivo.

The SDI molecules of the present invention are expressed
30 at a higher level in senescent than in actively cycling cells. Thus, lack of proper CDK activity through the regulatory action of SDI-1 could be a key reason for the inability of senescent cells to enter S phase. This is supported by the fact that senescent cells are primarily deficient in events downstream
35 of the postulated SDI-1 mediated inhibition of CDK2.

Overexpression of E2F-1, a component of the E2F-1 transcription factor which has a wide range of target genes, was found to be capable of reversing the inhibitory effect of

SDI-1. It is well established that the tumor suppressor gene Rb, as well as the related p107 protein complexes with E2F-1 to inhibit transcription. Overexpression of cyclins A and E reverses pRb-mediated suppression of proliferation. In addition, overexpression of E2F-1 can induce quiescent REF-52 cells to synthesize DNA. Thus, in view of the observation that E2F-1 reverses the negative growth activity of SDI-1, E2F-1 may be the last step in a cascade of events controlled by p53, SDI-1 and Rb.

10

EXAMPLE 12

THE RELATIONSHIP BETWEEN CELLULAR TUMOR SUPPRESSORS AND SDI SEQUENCES

15 A role for SDI-1 in cell cycle arrest is indicated by the fact that in normal human cells made quiescent either by serum deprivation or growth to high density, SDI-1 mRNA levels were increased 10-20 fold compared with cycling cells. However, upon addition of serum, SDI-1 mRNA levels were found to rapidly decrease to low levels just prior to the onset of DNA synthesis. Thus SDI-1 appears to act as a "check point" to inhibit cell proliferation in the presence of unfavorable external conditions. Many immortal cell lines are unable to block initiation of DNA synthesis in response to insufficient growth factors. However, in accordance with the present invention, the overexpression of SDI-1 in various immortal human cells resulted in inhibition of DNA synthesis in several of the cell lines regardless of their ability to arrest cell proliferation in response to lowered growth factors.

25 30 The physiological significance between the overexpression of SDI-1 and the inhibition of cell proliferation by overexpression of SDI-1 is strengthened by the finding that SDI-1 can inhibit the kinase activity of cyclin/cdk2 complexes. Indeed, as indicated the addition of 250 ng of purified GST-SDI-1 fusion protein to cyclin/cdk2 complexes (immunoprecipitated from HeLa cell extracts by cdk2 antisera) resulted in half maxial inhibition of histone H1 kinase activity.

35 In order to further investigate the molecular mechanism through which SDI-1 mediated its anti-proliferative activity,

the steady-state levels of SDI-1 RNA were evaluated in a number of immortal cell lines, including MDAH 041. The MDAH 041 cell line was derived from a Li-Fraumeni syndrome patient, and does not synthesize p53. The cells were found to be able to
5 continue to synthesize DNA in the presence of low serum growth factors.

SDI-1 levels were determined by northern analysis and were normalized to either GAPDH or b-actin mRNA. DNA was introduced by electroporation. Rapidly growing cells were
10 trypsinized and 10^6 cells were resuspended in 0.5 ml phosphate buffered saline along with 10 μ g of carrier DNA, 1 μ g of pCMVb (MacGregor, G.R. *et al.*, *Nucl. Acids Res.* 17:2365 (1989)) coding for the b-galactosidase gene and 1 μ g pCMVSDI-1 (containing nucleotides 1-685 of SDI-1). Plasmid pCMVb served as a
15 marker to detect cells that were capable of incorporating and expressing exogenous DNA. Following a pulse of 250-350 volts, 3×10^5 cells were seeded into 35 mm cell culture dishes. Tritiated thymidine (1 μ Ci/ml) was added to the culture medium 24-30 hours after electroporation and the cells were
20 incubated for an additional 24 hours. The cells were fixed, stained for b-galactosidase activity, and processed for autoradiography to determine the percentage of b-galactosidase positive cells that had synthesized DNA in the presence of the tritiated thymidine. The percent inhibition was
25 determined relative to control cells that were transfected with pCMV vector and pCMVb. Calcium transfection was used in the case of MDAH 041 cells. The correlation between SDI-1 mRNA levels and DNA synthesis is presented in Table 6. The data presented are averages of at least two experiments.

30

Table 6: Correlation between SDI-1 mRNA Level and Inhibition of DNA synthesis			
Cell Line	% Inhibition	SDI-1 mRNA level	P53 Status
MDAH 041	95 \pm 4	Not Detectable	Mutant
SAOS2	47	Not Done	Mutant
TE85	75 \pm 7	Not Detectable	Mutant
T98G	35 \pm 5	Not Detectable	Mutant
Hela	60 \pm 5	Low	HPV-18 infected
A1698	15 \pm 3	Normal	Wild-type
UABC023 Ser 31 \rightarrow Arg 31 Homozygous	57 \pm 6	Low	Unknown
GM639	78	Normal	SV40-transformed
GM847 Ser 31 \rightarrow Arg 31 Heterozygous	21	Normal	SV40-transformed
RN13	No Inhibition	Normal	Unknown
PR282	No Inhibition	Normal	Unknown

As indicated in Table 6, SDI-1 mRNA levels were found to be very low or undetectable in several cell lines which also lacked wild type p53 protein. Significantly, SDI-1 RNA and protein was undetectable the MDAH 041 cells. The correlation between p53 level and SDI-1 level suggested that p53 mediated its tumor suppressing activity by inducing a senescent state through the induction of SDI-1, and that cells which lacked p53 were neoplastic due to their inability to induce SDI-1 expression.

In view of the well established role of p53 in cell growth control and as a transcriptional activator or suppressor, and the fact that MDAH 041 cells do not express wild type p53, the finding that they also lacked SDI-1 expression indicated that the introduction of p53 into these cells would result in an induction of SDI-1 expression and thus, in growth arrest.

To further demonstrate the ability of p53 to induce SDI-1 expression, p53 was introduced into MDAH 041 cells. Such introduction resulted in increased expression of SDI-1 and in

the inhibition of DNA synthesis, as measured by tritiated thymidine autoradiography. The degree of inhibition increased with the amount of p53 plasmid introduced. If the inhibition of DNA synthesis observed was due to an induction of SDI-1 by p53, rather than by some other effect of p53, the inhibitory activity would be lost following co-transfection of antisense SDI-1 sequences.

Therefore, to demonstrate the direct induction of SDI-1 by p53, the above-described SDI-1 and antisense SDI-1 gene sequences were co-transfected with a p53 gene construct into normal human fibroblasts. As expected, the antisense construct was found to eliminate 80% of the inhibition of DNA synthesis caused by SDI-1 alone. When 4 μ g of SDI-1 and increasing amounts of p53 plasmids were co-transfected into MDAH 041 cells, the antisense SDI-1 was found to be capable of effectively counteracting the inhibition of DNA synthesis caused by p53 alone. These findings are summarized in Table 7. This finding verified the conclusion that one manner in which p53 causes inhibition of DNA synthesis is by activating the expression of SDI-1 and that such induction of SDI-1 is a requisite for part of the DNA synthesis-inhibitory activity of p53. Such activation occurs, at least in part, by the transcriptional activation of the SDI-1 gene. The expressed SDI-1 protein acts, in part, by inhibiting the kinase activities of CDK/cyclin complexes and can therefore act at multiple points in the cell cycle to block progression. Loss of wild type p53 activity would lead to lack of expression of SDI-1 and thereby result in inappropriate cell cycle progression.

Table 7: The Induction of SDI-1 by P53		
Amount of P53 DNA Transfected (ng)	DNA Synthesis (as approx. % of control)	
	P53 Alone	P53 + anti-SDI-1
0	100	121
10	25	50
30	15	45
100	10	25

Mutations in the gene encoding the p53 protein are common in human tumors with approximately 50% of tumors

expressing a mutant p53. This has led to the conclusion that p53 acts as a negative growth regulator and is a tumor suppressor gene. One aspect of the present invention concerns the recognition of the molecular mechanism responsible for the anti-oncogene activity of p53. SDI-1 has been found to be an inhibitor of cell cycle progression which acts at least in part by inhibiting the kinase activities of cdk/cyclin complexes. As such it can act at multiple points in the cell cycle to block progression. Since p53 is required for transcriptional activation of SDI-1, inactivation of this function could allow uncontrolled and inappropriate cell cycle progression. This would allow cells to ignore the normal external signals for cell cycle stasis and permit proliferation in situ. Since SDI-1 is downstream of p53, SDI-1 appears to be the effector of p53 action. Furthermore, mutations have been found in SDI-1 which may contribute to altered cell proliferation in cells without mutated p53.

EXAMPLE 13

CAPACITY OF SDI-1 TO SUPPRESS THE PROLIFERATION OF TUMOR CELLS

As indicated above, SDI-1 has the capacity to suppress the proliferation of tumor cells. To demonstrate this ability, cells derived from several human tumors were incubated in the presence or absence of a glutathione S-transferase-SDI-1 fusion protein. In the experiment, 5×10^3 cells were plated overnight at 37° C (only for adherent cells) and then incubated with the SDI fusion protein. After 48 hours at 37° C, cells were pulsed with thymidine for 24 hours and then harvested. The results of this experiment are shown in Table 8; the thymidine incorporation by untreated cells was expressed as 100%. all determinations were made in quadruplicate.

Table 8: Antiproliferative Effects of SDI-1		
Cell Line	Relative Cell Viability (% of Control)	
	50 μ g/ml	30 μ g/ml
Myeloid Cells:		
Promyelocytic (HL-60)	1 \pm 0	1 \pm 0
Promonocytic (ML-1)	1 \pm 0	1 \pm 0
Myelogenous (KG-1)	1 \pm 0	1 \pm 0
Myelogenous (KG-1a)	1 \pm 0	1 \pm 0
Histiocytic Lymphoma (U-937)	1 \pm 0	1 \pm 0
Promonocytic (THP-1)	1 \pm 0	1 \pm 0
B Cell Lymphoma		
Burkitt Lymphoma (Daudi)	1 \pm 0	3 \pm 0
Burkitt Lymphoma (Raji)	1 \pm 0	1 \pm 0
Epithelial Cells		
Breast (BT-20)	1 \pm 0	1 \pm 0
Breast (BT-20 TNF R)	1 \pm 0	1 \pm 0
Breast (SK-BR3)	1 \pm 0	1 \pm 0
Breast (MCF-7)	1 \pm 0	1 \pm 0
Breast (T-47 D)	2 \pm 0	2 \pm 0
Lung adenocarcinoma (A-549)	25 \pm 3	40 \pm 1
Hepatocellular (Hep G2)	12 \pm 2	21 \pm 3
Glioblastoma Cells		
Glial (U-251)	35 \pm 2	66 \pm 4
Normal Cells		
Human umbilical vein endothelial cells	2 \pm 1	5 \pm 1
Human foreskin fibroblasts	1 \pm 0	Not Done
Murine Tumor Cells		
Fibroblasts (L-929)	4 \pm 1	Not Done

The above experiment indicates that tumor cells treated with SDI-1 exhibited a profound suppression of DNA synthesis.

EXAMPLE 14

5 EFFECT OF SDI-1 cDNA ON THE PROLIFERATION OF TUMOR CELLS

The capacity of SDI-1 cDNA to repress the proliferation of tumor cells was evaluated. SDI-1 cDNA was introduced into a number of tumor derived and other cell lines by electroporation. One μ g of the CMV-SDI-1 plasmid was mixed

with 1 µg of plasmid containing the CMV promoter and the β-galactosidase gene. After electroporation, cells were plated and 24 hours later assayed for the ability to incorporate tritiated thymidine. SDI-1 cDNA caused significant inhibition of DNA synthesis in a number of tumor derived cell lines including a melanoma, lung tumor and a brain tumor. The SDI-1 cDNA also inhibited DNA synthesis in mouse 3T3 cells and in normal bovine smooth muscle cells. Three tumor derived cell lines (one lung tumor cell line, and two kidney tumor cell lines) were unresponsive to the SDI-1 cDNA.

EXAMPLE 15

EFFECT OF SDI-1 ANTISENSE cDNA ON THE PROLIFERATION OF NORMAL CELLS

The effect of SDI-1 on DNA synthesis was also evaluated using antisense expression vectors. SDI cDNA was provided to cells by introducing plasmid pCMVSDI684 which is a derivative of plasmid pCMVβ that lacks the β-galactosidase gene, and which contains nucleotides 1-684 of the SDI-1 cDNA sequence. Antisense vectors were constructed by cloning SDI-1 antisense sequences into pMET, an inducible expression vector containing an altered human metallothionein promoter (CSIRO, Biomolecular Engineering, New South Wales, AU). The promoter contains a deletion in the basal promoter and the addition of synthetic metal response elements in triplicate. For construction of pMET, adenovirus sequences containing E1A gene 12S and 13S introns (i.e. nucleotides 917-1673) were first cloned into the mammalian expression vector pRc/CMV (Invitrogen) at the NotI/ApaI sites of the multiple cloning region of this plasmid to create pRc/CMV-Ad. To ensure that no translation of E1A sequences occurred, and to create an SPEI cloning site in the vector, an SPEI linker containing a stop codon was inserted between the CMV promoter and the E1A splice sequence in-frame with the E1A sequence. The CMV promoter of plasmid Rc/CMV-Ad was then replaced with the pM26 promoter to create pMET.

To accomplish this, the metallothionein promoter was excised from pM26 by BglII digestion and inserted into the BamHI site of pBluescript (Stratagene). An EcoRV and NotI

fragment containing the promoter was then subcloned from pBluescript into a filled-in BglII site and NotI site of Rc/CMV-Ad. Antisense sequences from the SDI-1 cDNA were derived from the full length cDNA cloned into the BamHI site of pBluescript. The StuI site at nucleotide 127 was converted to a SpeI site by insertion of an SpeI linker to make SDISPE127. An SpeI linker was also inserted at the ApaI site at nucleotide 319 to create SDISPE319. These constructs were digested with SpeI and inserted in antisense orientation into the SpeI cloning site of pMET, thus creating the SDI antisense expression vectors pMET-AS127 (having the first 127 nucleotides of the antisense strand to SDI-1 cDNA, SEQ ID NO:1) and pMET-AS318 (having the first 319 nucleotides of the antisense strand to SDI-1 cDNA, SEQ ID NO:1).

Cell lines expressing SDI-1 antisense were obtained by calcium phosphate transfection. 3×10^5 HCA2 cells (human foreskin cells) at population doubling 10 were transfected with 20 μ g pMET, pMETAS127, or pMETAS318. Following two weeks of G418 selection, colonies were picked and expanded. Inducibility and integrity of the inserted sequence was determined using stable transformants by addition of 100 μ M ZnCl₂ and 2 μ M CdCl₂ followed by RNA analysis of total cell RNA. The analysis was an RNase protection using antisense RNA probes, internally labeled with [³²P]-UTP. The probe pMET+SDI-1, containing SDI-1 nucleotides 444-686 (of SEQ ID NO:1), was used to measure the expression of SDI-1 from both the transfected genes and endogenous mRNA. After EcoNI digestion, transcription from the SP6 promoter in the pMET vector resulted in an antisense labeled probe that hybridized to both RNA from the expression vector and to endogenous SDI-1 mRNA. This allowed a comparison of relative levels of expression from the introduced construct and SDI-1 endogenous RNA. As a control, β -actin mRNA was measured in all assays.

In order to determine the extent of DNA synthesis, the cells were trypsinized and 1×10^4 cells were seeded per well in 24 well plates. Four to six hours after plating, the cells were washed 3 times with phosphate buffered saline and the medium was replaced with medium containing 0.5% fetal bovine

serum. This serum deprivation induced the cells to become quiescent. Six to ten days later, the medium was replaced and metal was added to induce the metallothionein promoter. The amount of metal added was optimized for each plasmid; optimized amounts were 70 μM ZnCl_2 and 1.4 μM CdCl_2 for pMET1 and 50 μM ZnCl_2 and 1 μM CdCl_2 for AS1. Twenty hours later, induction was boosted by the addition of fresh medium. $[^3\text{H}]$ -thymidine (1.5 $\mu\text{Ci/ml}$) was added to each culture 4 hours later. Twenty-four hours later, cells were fixed and analyzed by autoradiography. The results obtained in a typical experiment are shown in Table 9, and demonstrate the capacity of the antisense molecules of the present invention to induce the proliferation of quiescent cells.

Table 9		
Cell Line	% of Cells Labeled	
	Before Metal Induction	After Metal Induction
No Integrant	<5%	5%
Vector Control	<5%	5%
Antisense Construct I	7%	49%
Antisense Construct II	<5%	57%

EXAMPLE 16
ABILITY OF SDI-1 ANTISENSE OLIGONUCLEOTIDES TO REPRESS
THE SDI-MEDIATED INHIBITION OF PROLIFERATION

As discussed above, the expression of SDI-1 inhibits DNA synthesis. In some instances, such as to immortalize human cells in culture, it is desirable to repress such inhibition. The SDI-1 antisense molecules of the present invention are capable of mediating such repression.

In order to demonstrate the capacity of SDI-1 antisense oligonucleotides to repress the DNA synthesis-inhibitory effects of SDI-1, cells were provided with an oligonucleotide having the sequence:

SEQ ID NO:3

AGCCGGTTCTGACATGGCG

This oligonucleotide is antisense to SEQ ID NO:1 at nucleotides 75-93.

Cells were cultured in medium containing 10% fetal bovine serum (FBS) for approximately one week, at which time the medium was replaced with medium containing 0.5% FBS. The cells were divided into control cells and experimental cells. On Day 1, experimental cells were provided with either 1, 2 or 5 μ M of the above-described oligonucleotide; Control cells received no oligonucleotide. On Day 3, and again on Day 5, all cells received fresh medium containing 0.5% FBS; experimental cells received additional oligonucleotides (1, 2 or 5 μ M). On Day 6, tritiated thymidine was added to the culture media and the cells were harvested on day 7. Experimental cells (that had received the antisense oligonucleotide) exhibited an increase in the amount of tritiated thymidine incorporated into their DNA, relative to the control cells.

The results indicated that oligonucleotides that contain regions complementary to SDI-1 nucleotides 75-93 can act as antisense repressors of SDI-1 function.

EXAMPLE 17

EFFECT OF DNA DAMAGE AND GROWTH ARREST ON THE EXPRESSION OF SDI-1

The above-described experiments demonstrated that p53 induces SDI-1 expression, and that the production of SDI-1 mRNA was induced in contact-inhibited and serum-deprived cells, as well as in senescent human cells. To determine whether the induction of SDI-1 was a general characteristic of growth arrest states, the effect of DNA damage on SDI-1 mRNA levels was evaluated.

Cells are believed to undergo growth arrest in response to DNA damaging agents before entering the S or M phases of the cell cycle. The growth arrest permits the cell to repair any genetic lesions caused by the DNA damaging agents. A failure to repair such damage creates a mutation, and may have severe consequences ranging from cell death to neoplasia. Thus, the capacity of a cell to undergo growth arrest in response to DNA

damage has great importance both in the etiology of cancer and in the response of cancer cells to chemotherapy.

To evaluate the effect of DNA damaging agents on SDI mRNA production, normal human neonatal foreskin fibroblast cells (strain HCA2); an immortalized cell line (TE85, obtainable from the American Type Culture Collection, Rockville, MD, US), and the above-described MDAH 041 cell lines were employed. All cells were cultured in Eagle's minimal essential medium with Earl's salts plus 10% fetal bovine serum (Gibco BRL, Gaithersburg, MD, US) in 5% CO₂ at 37° C, or in Hanks salts plus 10% fetal bovine serum at 37° C. HCA2 cells achieve approximately 80 population doublings before becoming senescent. The cells were used at population doubling 27 or less.

Cells were plated at 1×10^4 cells/cm² on glass coverslips and grown 24-48 hours to 50-75% confluency and were then treated with one of several DNA damaging agents: γ -rays (4 Gy); bleomycin (75 μ g/ml; 4 hours), etoposide (400 μ M in 4% DMSO; 8 hours), hydrogen peroxide (400 μ M; 1 hour), UV light (30 J/m²), methyl methane sulfonate ("MMS") (100 μ g/ml; 4 hours), mitomycin C ("MMC") (5 μ g/ml; 30 hours) and CdCl₂ (250 μ M; 1 hour). For UV irradiation, cells were cultured in 150 cm² tissue culture dishes. Immediately prior to treatment the medium was removed and the dishes, without lids, were placed in a Stratagene (La Jolla, CA, US) StratalinkerUV cross-linking device and irradiated with a dose of 30 J/m². Fresh serum-supplemented medium was then added and the cells were incubated at 37° C, 5% CO₂. γ -irradiation was performed on cells in complete cell culture medium in 25 cm² tissue culture flasks, using a fixed ¹³⁷Cs source. The dose rate was 4.21 Gy/min. Exposure was to 4 Gy. In addition, the effects of heat shock (42° C; 4 hours), hydroxyurea (2 mM; 24 hours) and prostaglandin A₂ (10 μ g/ml in 0.1% ethanol; 24 hr) were evaluated.

Tritiated thymidine was added 16 hours following each such treatment and the cells were incubated for 8 hours, fixed and processed for autoradiography as described above. RNA was harvested 4 or 24 hours post treatment using RNazol B

(Cinna/Biotechx, Houston, TX.) according to the manufacturer's protocol. 10-20 μ g of RNA was separated on a 1.2% agarose gel with 20% formaldehyde, transferred to a Gene screen plus (EN, Boston, MA) membrane, probed, and quantitated. Fold induction was determined by comparing treated samples with untreated controls. Controls were mock treated cells put through the same washing, media change, transportation, and inadvertent temperature fluctuation as those receiving treatment. Controls for agents dissolved in ethanol or dimethyl sulfoxide were exposed to the same concentration of the solvent alone. SDI-1 RNA values were normalized to GAPDH levels. In some cases normalization to actin RNA was also done and revealed no substantial differences in fold induction. The results of this experiment are shown in Table 10.

15

Table 10: Induction of SDI-1 mRNA and Growth Arrest by Various Treatments				
Mechanism of Action	Agent	Dose	SDI-1 Level*	% Growth Arrest
Double-Stranded Breaks	γ -ray	4 Gy	2.0	70%
Double-stranded Breaks	bleomycin	75 μ g/ml 4 hr	11.8	100%
Protein Associated Double-Stranded Breaks	etoposide	400 μ M 8 hr	8.0	100%
Free Radicals	H ₂ O ₂	400 μ M 1 hr	6.3	95%
Bulky Adducts (some free radicals)	UV light	30 J/m ²	15.2	60%
Alkylation	MMS	100 μ g 4 hr	3.27	53%
Cross-Linking	Mitomycin C	5 μ g/ml 30 hr	2.8	100%
Mutagenic Metal	CdCl ₂	250 μ M 1 hr	1.3	0%
General Stress	Heat Shock	42° C 4 hr	2.3	Not Done
Inhibitor of dNTP Synthesis	hydroxyurea	2 mM 24 hr	7.9	100%
Paracrine Hormone	prostaglandin A ₂	10 μ g/ml 24 hr	6.1	100%
* Fold induction of SDI-1 at 24 hour level				

5 Preliminary studies (El-Deiry, W.S. *et al.*, *Cell* 75:817-825 (1993)) suggested that the production of WAF1 might be induced by UV light. The above experiments demonstrate that the production of SDI-1 mRNA is induced by DNA damage and other growth arrest treatments in both normal cells and cells that lack wild type p53. The results of the above-described experiment demonstrate the role of SDI-1 in the repair of DNA damage or mutations that could lead to neoplasia in mammalian cells.

10 Every agent studied, with one exception, was found to cause an increase in SDI-1 mRNA in these cells (Table 10). Cadmium chloride, at the concentration used, failed to increase SDI-1 message level. However, tritiated thymidine

incorporation analysis revealed that the cadmium chloride treatment did not induce growth arrest (no inhibition of DNA synthesis) (Table 10). In contrast, growth arrest, as measured by tritiated thymidine incorporation, was essentially complete in response to the other agents tested (Table 10). However, in the case of UV irradiation and MMS treatment, an inhibition of only 50-60% was observed. It is possible that growth arrest, in response to these agents, had not reached its maximum at the time DNA synthesis was measured or conversely that cell proliferation had already resumed. The lack of induction by cadmium chloride indicates that SDI-1 message was increased by DNA damage only when the damage caused growth arrest. This is supported by the observation that hydrogen peroxide was unable to further elevate SDI-1 mRNA levels in cells that were already growth arrested by contact-inhibition.

The kinetics of SDI-1 RNA induction by γ -irradiation and hydrogen peroxide treatment was found to differ (Figure 6), providing further evidence for multiple mechanisms involved in regulating SDI-1 gene expression. Induction of SDI-1 message by γ -irradiation follows a time course for this gene by p53. It has been demonstrated in mouse prostate cells that p53 activity increases rapidly (within 30 minutes) following exposure to ionizing radiation and then declines to baseline level within 3 hours (Lu, X. *et al.*, *Cell* 75:765-778 (1993)). The induction of SDI-1 mRNA observed in normal human cells is similar to this pattern though lagging in time slightly as would be expected. The major difference is that SDI-1 message declined more slowly (over approximately 30 hours) than p53 activity, thus explaining the observation of Lu, X. *et al.* (*Cell* 75:765-778 (1993)). The induction of SDI-1 mRNA observed in normal human cells is similar to this pattern though lagging in time slightly. The major difference is that SDI-1 message declined more slowly (over approximately 30 hours) than p53 activity. This explains the observation of Lu, X. *et al.* (*Cell* 75:765-778 (1993)), that ionizing radiation-induced arrest lasts for 20-30 hours, long after p53 activity had declined.

Induction of SDI-1 message by hydrogen peroxide (Figure 6) exhibited a very different pattern. It has been proposed that

exposure to hydrogen peroxide results in a rapid increase in p53 activity (Tishler, R.B. *et al.*, *Canc. Res.* 53:2212-2216 (1993)), which returns to baseline by 4 hours post-treatment. SDI-1 mRNA level, in contrast, did not rise significantly until 9 hours after treatment and continued to increase for at least 48 hours (Figure 6). The slow response of SDI-1 RNA level to hydrogen peroxide treatment indicates that while an elevated level of SDI-1 mRNA appears to be universally associated with growth arrest, it may not always be the initial cause of the arrest. A similar pattern of SDI-1 message elevation was observed by serum-deprivation and contact-inhibition of normal human cells and resembles what is observed in cases of mRNA stabilization. A slow increase of mRNA in response to serum-deprivation and contact-inhibition has also been noted for the GADD genes (Fornace, A.J. *et al.*, *Molec. Cell. Biol.* 9:4196-4203 (1989)). In all these cases, SDI-1 may act to maintain growth arrest after it has been initiated by another pathway.

EXAMPLE 18

ROLE OF P53 IN THE SDI-1 RESPONSE TO DNA DAMAGE AND GROWTH ARREST

As indicated, agents that cause growth arrest but do not damage DNA (heat shock, hydroxyurea, and prostaglandin A₂) were also examined (Table 10) and found to cause an increase in SDI-1 message levels. Heat shock and hydroxyurea treatments increased SDI-1 message (Table 10) though both have been shown not to increase p53 activity (Lu, X. *et al.*, *Cell* 75:765-778 (1993); Zhan, Q. *et al.*, *Molec. Cell. Biol.* 13:4242-4250 (1993)), indicating these agents may operate through a p53-independent mechanism.

In order to further investigate this possibility, the p53 status of various immortal cell lines was determined through immunoprecipitation studies and compared to the steady state level of SDI-1 mRNA in the same cell lines. For this purpose, cell lines were grown to approximately 70% confluence in 75 cm² flasks prior to being cultured for 1 hour in methionine-free modified Dulbecco's Eagle medium, and then labeled in methionine-free medium containing 10% dialyzed fetal bovine serum and 100 μ Ci/ml L-[³⁵S] methionine (TRAN35SLABEL;

ICN). One flask was used per immunoprecipitation. After a 3 hour incubation in this labeling medium, the cells were placed on ice, washed with ice-cold phosphate buffered saline (PBS) and harvested in lysis buffer (20 mM Tris, pH 7.4, 150 mM NaCl, 0.5% NP-40, 1 mM EDTA, 50 µg/ml leupeptin, 30 µg/ml aprotinin). Lysates were scraped into microfuge tubes and sheared 3 times by passage through a 25 gauge needle. Phenylmethylsulfonyl fluoride was added to a final concentration of 1 mM and lysates centrifuged at 14,000 r.p.m. in an Eppendorf microfuge at 4°C for 45 min. Supernatant volumes were adjusted to normalize for cell number, then precleared for 30 minutes at 4° C for 45 min. Supernatant volumes were adjusted to normalize for cell number, then precleared for 30 minutes at 4° C on a rotating wheel with approximately 40 µl packed volume of protein A-agarose (Pharmacia) that had been sequentially coated with rabbit anti-mouse IgG (ICN) and a mixture of two mouse IgG2a myeloma proteins (ICN). Lysates were then microfuged and each resulting supernatant was incubated with 50 µl packed volume of protein G PLUS/Protein A-agarose (Oncogene Science) coated with 4 µg of an appropriate p53-specific antibody or a nonspecific antibody of the same class and subclass. Specific antibodies were PAb421, which binds both wild-type and mutant forms of P53, PAb 240, which recognizes a subset of mutant forms, and PAb1620, which recognizes wild type p53 specifically. All p53 antibodies were obtained from Oncogene Science. Non-specific antibodies used were either a non-specific IgG₁ antibody to *E. coli* anthranilate synthases protein or a mixture of two IgG2a myeloma proteins. Incubations were carried out for 2 hours at 4° C on a rotating wheel. Samples were microfuged and pellets washed 4 times with ice-cold wash buffer (20 mM Tris, pH 7.5, 150 mM NaCl, 0.5% NP-40, and 0.1% SDS) then 2 times with PBS. Samples were resuspended in 2X loading buffer (4% SDS-polyacrylamide gel, pH 8.8. The gel was fixed, treated with Amplify (Amersham), dried and exposed to Kodak X-AR film for 20-28 hours at 80° C.

If p53 had been the only regulator of SDI-1 mRNA transcription, the absence of wild type p53 would have

coincided with a low level of SDI-1 expression, whereas, the presence of functional p53 should have corresponded to a higher level of SDI-1 expression.

Evidence for a p53-independent mechanism of regulation of SDI-1 expression was obtained by exposing TE85 and MDAH 041 cells, which lack functional p53, to many of the agents described in Table 10 and determining changes in SDI-1 message levels. TE85 is an osteosarcoma derived line, which has been found, by immunoprecipitation, to express only mutant p53. All treatments examined except γ -irradiation, which requires wt p53 for G₁ arrest (Kuerbitz, S.J. *et al.*, *Proc. Natl. Acad. Sci. USA* 89 :7491-7495 (1989)), were able to increase SDI-1 message in the cell line TE85 (Table 11). The p53-independent upregulation of SDI-1 RNA level was confirmed in MDAH041 cells following hydrogen peroxide and hydroxyurea treatment (Table 11). The pattern of SDI-1 mRNA accumulation is therefore similar to that of GADD45. This gene also requires functional p53 for induction by γ -irradiation but not by most other agents (Zhan, Q. *et al.*, *Molec. Cell. Biol.* 13:4242-4250 (1993)). GADD45 is a member of a family of genes that were identified based upon their induction by both growth arrest and DNA damage (Fornace, A.J. *et al.*, *Molec. Cell. Biol.* 9:4196-4203 (1989)). These findings indicate that P53 is not the only regulator of SDI-1, and that additional regulators of SDI-1 exist. The above methods can be used to identify such additional regulators.

Table 11		
Agent	TE85	MDAH 041
Control	1	1
γ -rays	1.3	1.1
etoposide	2.6	
H ₂ O ₂	4.0	3.3
UV light	3.0	
MMS	4.4	
MMC	2.5	
Hydroxyurea	7.5	2.5

In summary, the above results demonstrate that: 1) a wide variety of agents that induce growth arrest, including those that damage DNA, elevate SDI-1 message level; 2) some agents can accomplish this in the absence of functional P53 and 3) this elevation follows two distinct temporal patterns. In one, a rise in p53 activity results in a parallel increase in SDI-1 mRNA. This occurs early enough to be causative of arrest. In the second, an inhibitor of growth causes arrest by a mechanism that does not depend entirely upon p53. This arrest is associated with a gradual accumulation of SDI-1 mRNA, perhaps due to an increase in message stability.

EXAMPLE 19

PRODUCTION OF MONOCLONAL ANTIBODIES TO SDI-1 FUSION PROTEINS

Anti-SDI-1 monoclonal antibodies were isolated as described above using the GST-SDI-1 fusion as an immunogen and using the [His]₆ fusion having the leader sequence of SEQ ID NO:4 in a screen for suitable hybridomas. All of the antibodies could immunoprecipitate both cellular and recombinant SDI-1 protein in addition to the GST-SDI-1 fusion protein.

The monoclonal antibodies were used to in an immunohistochemical evaluation of human tissue. Antibodies (10 µg/ml) from four hybridoma lines (18A10; C6B6; 8A8; 2G12), and from a mouse IgG2b control, were incubated with neat supernatant overnight at 4 °C. Antibody was detected using the Vector Standard ABC kit with DAB as chromogen. Tissue from human tonsil (containing both a lymphoid and an epithelial cell component), adult human skin (containing both connective tissue and epithelial cell components) or adult human colon (containing connective tissue and glandular epithelial cell components) was evaluated. Staining was evaluated on a qualitative +/- scale. The control antibody failed to elicit staining on any tissue.

Monoclonal antibody 18A10

- 5 Tonsil all epithelial cell layers, all lymphocytes and
 all stromal components did not stain.
- Skin all upper layers and possibly the basal cell
 layer showed a trace to 1+ diffuse cytoplasmic
 staining. The connective tissue components did
 not stain.
- 10 Colon Epithelial cells did not stain. The mucous
 within the glands exhibited a trace to 1+
 staining. The connective tissue components did
 not stain.

Monoclonal antibody C6B6

- 15 Tonsil all epithelial cell layers, all lymphocytes and
 all stromal components did not stain.
- Skin basal cell epithelial cells had a +/- to trace+
 diffuse cytoplasmic staining. The connective
 tissue components did not stain.
- 20 Colon Individual cells among the epithelial cells
 showed a 3+ nuclear/cytoplasmic staining. The
 mucous within the glands did not stain. The
 connective tissue components did not stain.

Monoclonal antibody 8A8

- 25 Tonsil all upper layer epithelial cell layers and
 possibly basal cells showed a +/- to trace+
 diffuse cytoplasmic staining. Lymphocytes and
 all stromal components did not show immuno-
 reactivity.
- 30 Skin all upper epithelial cells showed a +/- to 1+
 diffuse cytoplasmic staining. The connective
 tissue components did not stain.
- Colon Areas of epithelial cells showed a 3+
 nuclear/cytoplasmic staining. The mucous
 exhibited a +/- staining. The connective tissue
 components did not stain.

Monoclonal antibody 2G12

- 5 Tonsil the basal cell epithelial layer showed a trace to 1+ staining. Some lymphocytes exhibited a trace membrane staining. The stromal components did not stain.
- Skin the basal cell layer showed a trace to 1+ diffuse cytoplasmic staining. The upper cell layers did not appear to stain.
- 10 Colon Significant brown precipitated material was evident, suggesting that some ductal epithelial cells were exhibiting a strong nuclear stain. The mucous within the glands did not stain. The connective tissue components did not stain

15 The experiment indicated that the monoclonal antibodies could distinguish between tissue types that expressed SDI-1 and those that did not express SDI-1. Moreover, it was possible to discern a differential pattern of staining in different cell types. The immunohistochemical evaluation could be performed on biopsied tissue. The detection of non-staining foci of cells

20 within the tumor mass would be indicative of cells that no longer expressed SDI-1, and which therefore would warrant more aggressive antineoplastic and antimetastatic therapy.

EXAMPLE 20

25 DELIVERY OF SDI-1 TO TARGET CELLS

 The ability to deliver a pharmacological agent to a cell constitutes a general problem in defining therapeutic protocols. In order to evaluate the role of the GST moiety in facilitating the cellular uptake of SDI-1, the drug-delivery capacity of two

30 GST-SDI-1 constructs was evaluated.

Construction of the First GST-SDI-1 Fusion

 The first of these fusions was the especially preferred *Schistosoma japonicum* GST-SDI-1 fusion (discussed above)

35 that had been initially recognized as being capable of entering target cells. Remarkably, however, slight modifications in the structure of this fusion were found to substantially destroy its

capacity to be taken up by target cells. Thus, the originally described *Schistosoma japonicum* GST-SDI-1 fusion had inherent and distinctive characteristics that were not previously fully recognized.

5 The especially preferred *Schistosoma japonicum* GST-SDI-1 fusion was formed by cleaving plasmid pcDSR $\alpha\Delta$ -SDI-1 with Acyl and EcoRI, thereby liberating an SDI-1-encoding fragment. Acyl cleaves the plasmid 4 nucleotides preceding the SDI-1 initiation codon; EcoRI cleaves the molecule at
10 approximately position 1010 of SEQ ID NO:1. The fragment was then cloned between the SmaI and EcoRI sites of plasmid pBS. This construct was then cleaved with BamHI and EcoRI to release an SDI-1-encoding fragment that contained the nucleotides: GGATCCCCCGCC (SEQ ID NO:7) immediately
15 preceding the SDI-1 ATG initiation codon. The distal terminus of the molecule was at approximately position 1010 of SEQ ID NO:1.

Plasmid pGEX2T, which contains the *Schistosoma japonicum* GST-encoding sequence was cleaved with BamHI and
20 EcoRI. The BamHI enzyme cleaves the *Schistosoma japonicum* GST-encoding sequences at a site located at nucleotides 662-667 of the molecule (approximately at codon 226 of the molecule); the EcoRI enzyme cleaves the plasmid outside of the GST-encoding sequences. The dual enzymatic cleavage prevents
25 religation of the plasmid, and ensures that the SDI-1 sequences will be introduced in the proper orientation.

The BamHI-EcoRI treated pGEX2T DNA was incubated with the above-described SDI-1-encoding fragment that contained, at one end the nucleotides: GGATCCCCCGCC (SEQ ID NO:7)
30 immediately preceding the SDI-1 ATG initiation codon, and at the other end an EcoRI cleavage site. Ligation of the two molecules produced a plasmid in which the SDI-1-encoding sequences were fused one nucleotide out of frame from the GST-encoding sequences. In order to restore reading frame, the
35 plasmid was cleaved with BamHI, the staggered ends were filled in using Klenow DNA polymerase, and then ligated to a 10 base pair XhoI linker (Promega) having the sequence: CCCTCGAGGG (SEQ ID NO:8). Thus, the final construct contained

sequences encoding amino acids 1-226 of GST fused to a 9 residue fragment that encoded Pro-Arg-Gly (residues 1-3 of SEQ ID NO:9) fused to a BamHI-filled linker (SEQ ID NO:7) that encoded Asp-Pro-Pro-Ala (residues 4-7 of SEQ ID NO:9) fused
5 to the ATG initiation codon of SDI-1 and the remainder of the SDI-1-encoding sequence. The nucleotide sequence of the complete gene fusion is provided in SEQ ID NO:10; the amino acid sequence encoded by this gene fusion is provided in SEQ ID NO:11. An *E. coli* strain transformed with plasmid pAG20,
10 containing the above-described first GST-SDI-1 gene fusion was deposited with the American Type Culture Collection (Rockville, MD, U.S.) under the terms of the Budapest Treaty governing microbial deposits. The deposit was made on April 5, 1994, and was given the Deposit Accession Number ATCC
15 69597.

Construction of the Second GST-SDI-1 Fusion

The second SDI fusion was obtained by amplifying the SDI-1 coding region of plasmid pcDSR $\alpha\Delta$ -SDI-1 using the
20 polymerase chain reaction, and primers having the sequence:

Primer 12614 (SEQ ID NO:12)

GGAGGATCCATGTCAGAACCGGCT

Primer 12615 (SEQ ID NO:13)

25 GCAGAATTCCTGTGGGCGGATTAG

These primers amplify a polynucleotide containing residues 77-587 of SEQ ID NO:1. Primer 12614 has a BamHI site immediately upstream of the ATG translation initiation
30 site. Primer 12615 includes 14 nucleotides downstream of the translational stop site, and includes a partial EcoRI site.

The amplified product was cleaved with BamHI and EcoRI and cloned into the above-described BamHI/EcoRI treated pGEX2T plasmid. The resulting plasmid contained an in-frame
35 fusion linking codon 226 of the GST sequence to codon 1 of SDI-1.

The two protein fusions thus differ only in that the first fusion contains a "hinge region" consisting of the amino acids:

SEQ ID NO:9 Pro-Arg-Gly-Asp-Pro-Pro-Ala

whereas the second region does not contain any hinge region.

- 5 When the first and second GST-SDI-1 fusions were provided to young cells, the first fusion protein was found to be detectable within the cells whereas the second fusion protein was not detected within the cells. These observations indicated that whereas the first GST-SDI-1 fusion had the capacity to bind to cells and to be incorporated into recipient cells, the second GST-SDI-1 fusion lacked this capability. Consistent with these observations, of young cells that had been exposed to either the first protein fusion or the second protein fusion, only cells exposed to the first protein fusion exhibited quiescence.

- 15

EXAMPLE 21

DELETION ANALYSIS OF SDI-1 PROTEIN

- In order to investigate the functional domains of the SDI-1 protein, several genetic constructs were prepared in which the CMV promoter was used to drive transcription of fragments of the SDI-1 cDNA sequence.
- 20

- Specifically, SDI-1 polynucleotides were constructed that lacked codons for amino acids: 24-29 (designated as: SDI-1_{1-23;25-164}); 30-35 (designated as: SDI-1_{1-29;36-164}); 42-47 (designated as: SDI-1_{1-41;48-164}); 53-58 (designated as: SDI-1_{1-52;59-164}); 66-71 (designated as: SDI-1_{1-65;72-164}); 72-164 (designated as: SDI-1₁₋₇₁). In addition, an SDI-1 polynucleotide was constructed that had been treated to remove a Stu - Tth fragment that included codons 16-52 (designated as: SDI-1_{Stu-Tth}). These constructs, and an intact SDI-1-encoding construct (designated as: SDI-1₁₋₁₆₄) and a CMV control vector were co-transfected into MDAH 041 cells along with a vector that expressed β -galactosidase driven by the CMV promoter. The percent of growth inhibition was determined relative to cells that had been co-transfected with
- 25
- 30
- 35

the CMV- β -gal and CMV vector. Experiments were done in triplicate. The percent inhibition obtained for each SDI-1 polynucleotide is shown in Table 12.

Table 12					
Construct	Amino Acids Deleted	Percent Inhibition			
		Expt. 1	Expt. 2	Expt. 3	Avg.
CMV-vector	none	98	100	98	99
SDI-1 _{1-23;25-164}	24-29	93	93	92	93
SDI-1 _{1-29;36-164}	30-35	93	91	83	89
SDI-1 _{1-41;48-164}	42-47	66	76	75	72
SDI-1 _{1-52;59-164}	53-58	40	46	57	48
SDI-1 _{1-65;72-164}	66-71	88	81	88	86
SDI-1 _{Stu-Tth}	Stu-Tth	11	36	13	20
SDI-1 ₁₋₁₆₄	72-164	90	98	98	95

5 The results indicate that deletion of amino acids 42-47 caused a decrease in the efficiency and extent of inhibition. Deletion of amino acids 53-58 showed a major decrease in efficiency and extent of inhibition. Deletion of the carboxy terminal portion of the SDI-1 molecule (amino acids 72-164)
 10 did not significantly affect the extent of inhibition. Thus, active domains of SDI-1 are present within a peptide fragment containing amino acids 1-71, and amino acids 42-47 and 53-58 contain active SDI-1 domains. In sum, active domains of SDI-1 are contained between amino acids 42-58 of the SDI-1 protein.

15

EXAMPLE 22

THE IDENTIFICATION OF AN IMMUNOREACTIVE 23 KD PROTEIN

As expected, all of the above-described monoclonal and polyclonal antibodies were found to be capable of
 20 immunoprecipitating a 21 kD protein ("p21") corresponding to SDI-1. Analysis of the protein immunoprecipitated by these antibodies revealed that, unexpectedly, the antibodies also precipitated a 23 kD protein that was present in cellular extracts. The fact that all of the anti-SDI-1 antibodies tested
 25 precipitated this 23 kD protein ("p23") indicates that SDI-1

and the 23 kD protein are structurally related and share multiple epitopes. The fact that the 21 kD SDI-1 protein expressed from the above-described cDNA vectors is biologically active, indicates that the 23 kD protein exhibits the characteristics of an inactive, phosphorylated precursor of the active 21 kD SDI-1 protein.

In possessing such a precursor, SDI-1 resembles the Rb protein which has been found to exhibit multiple phosphorylation states that have molecular weights of 110-114 kD; the dephosphorylated form has a molecular weight of 110 kD (Lee, W.-H. *et al.*, In: *Tumor Suppressor Genes*, Klein, G. (ed.), Marcel Dekker, Inc., New York, pp. 169-200 (1990)).

The identification of an inactivated, phosphorylated form of SDI-1 would indicate that the biological activity of SDI-1 is both positively regulated by p53 induction of transcription and negatively regulated by a cellular kinase. The identification of such kinase(s) can be readily determined by screening a cDNA library for members that upon expression produce proteins that can increase the phosphorylation of dephosphorylated p21 SDI-1. Such conversion can be analyzed by conducting western blots of p21-p23 immunoprecipitated protein. Since such enzymes inactivate p21 SDI-1, they confer a proliferative capacity to the cell, and can be identified as molecules that overcome SDI-1-induced senescence. Such molecules can be employed in the same manner as SDI-1 antisense nucleic acids. Similarly, enzymes that dephosphorylate the p23 protein can be identified by screening for polynucleotides that, upon expression, form a protein that can convert the p23 form into the p21 form. Western blot methods can be used to identify such molecules. Since such enzymes convert the p23 molecule into the active p21 form, such enzymes confer a quiescent or anti-proliferative capacity to the cells. Such molecules can be employed in the same manner as SDI-1 or SDI-1 encoding nucleic acids.

EXAMPLE 23**CHARACTERIZATION OF SDI-1 FRAGMENTS**

As discussed above, the control of cell proliferation in eukaryotes from yeast to humans involves the regulated synthesis, activation, and degradation of a family of cyclins that act as the regulatory subunits of protein kinases termed cyclin-dependent kinases (Cdks). The cdks are necessary for the start of S phase and mitosis. The mechanism of inhibition of DNA synthesis by the protein SDI-1 involves inhibition of a series of Cdk kinase activities (e.g., cdk1-cdk6)). Indeed, *in vivo* SDI-1 protein has been found to associate with several of these cdk-cyclin complex by immunoprecipitation with antibodies against the various cyclin antibody (see, Xiong, H. *et al.*, *Cell* 71:505-514 (1992)). These complexes are disrupted upon cellular transformation with some DNA tumor viruses (PCT Patent Application WO94/09135; Waga, S. *et al.*, *Nature* 369:574-578 (1994)), confirming the above-stated mechanism by which oncogenic proteins alter the cell cycle of transformed cells. In addition, a recent report has confirmed the above-described relationship between SDI-1 and p53, and has shown that wild type p53 directly transactivates SDI-1 (Harper, J.W. *et al.*, *Cell* 75:805-816 (1993); El-Deiry, W.S. *et al.*, *Cell* 75:817-825 (1993); Xiong, Y. *et al.*, *Nature* 366:701-704 (1993); Dulic, V. *et al.*, *Cell* 76:1013-1023 (1994)), thus confirming that it is the downstream effector of p53. These results confirm that SDI-1 is not only a negative regulator during normal cell proliferation but also a tumor suppresser factor during carcinogenesis.

In order to determine the region(s) of the SDI1 molecule that was required to inhibit DNA synthesis, a series of plasmids was constructed in which various SDI-1 cDNAs, expressed from the CMV promoter, were progressively truncated from the 3' end of the coding region. The capacity of the deletion mutants to inhibit kinase activity and/or DNA synthesis was evaluated using a transient expression assay and binding assay with cdk2.

The plasmids were constructed by digesting the plasmid pCMV β with NotI to remove the *E. coli* β -galactosidase gene.

This site was blunted with Klenow and an SpeI linker was inserted in order to create pCMVSpeI. The full-length SDI-1 cDNA was digested with BamHI and DraI and cloned into a pBluescript vector. An SpeI linker was ligated into the Hinc

5 II site of this vector to create SpeI ends for nucleotides 1-686 of the SDI1 cDNA [plasmid pBSsdil(1-686)SpeI]. The SpeI-bounded fragment of SDI-1 from this vector was then ligated into the pCMVSpeI vector to create pCMVsdil(1-686), containing the full 164 amino acid coding region (SEQ ID NO:2)

10 for the wild-type SDI-1 cDNA sequence. A series of mutants encoding carboxy-terminal truncated versions of SDI-1 were generated using restriction enzymes that have unique sites within the SDI-1 coding sequence.

HCA2, the above-described normal human diploid

15 fibroblasts derived from neonatal foreskin were employed in the mutational analysis. These cells achieve 80 population doublings (PD) before entering senescence and were used at PD of 20-30 in all experiments. Each construct was tested for the ability to inhibit the initiation of DNA synthesis when

20 transfected into HCA2. Following transfection, the deletion constructs were tested for protein production by immunofluorescence using an anti-HA monoclonal antibody (12CA5, obtained from BabCO).

Transfection of the full length SDI1 coding region

25 resulted in a 90% decrease in the percentage of cells incorporating tritiated thymidine. A truncated SDI-1 encoding only the amino terminal 71 amino acids was as effective as the full length 164 amino acid protein in blocking entry into S phase whereas, a more severely truncated form encoding only

30 the first 52 amino acids was completely inactive (Table 13). This indicated that a critical region for the DNA synthesis inhibitory activity was located between amino acids 52 and 71. Thus, peptide fragments of SDI-1 having amino acid residues 52-71 comprise mimetics of SDI-1 protein. Similarly,

35 molecules that mimic a reactive side group of SDI-152-71 comprise mimetics of SDI-1. The role of the amino terminal portion of the protein in inhibiting entry into S phase was further clarified when a construct with a deletion in amino

acids 16-52 (plasmid "1 - 164 (Δ 16-52)") was also found to have lost all DNA synthesis inhibitory activity.

Table 13	
Amino Acid Residues Present In SDI-1 protein fragment	% Inhibition of DNA Synthesis Relative to Control
1 - 164	88%
1 - 123	90%
1 - 82	92%
1 - 71	85%
1 - 52	0%
1 - 16	0%
1 - 164 (Δ 16-52)	0%

5 To more finely map the DNA synthesis inhibitory region of
the molecule, small internal deletions (in which only 4 to 6
amino acids were removed and 3 amino acids (Pro-Arg-Gly)
were substituted) were introduced into the amino terminal
portion of the molecule that the large deletion constructs had
10 indicated was necessary for the inhibitory activity. Deletions
of six amino acids were constructed in the SDI-1 cDNA at
amino acids 24-29, 30-35, 42-47, 53-58 and 66-71. These
constructs were fused in frame with DNA encoding a portion of
the hemagglutinin (HA) molecule to provide an in-frame
15 hemagglutinin (HA) tag at the C-terminus of the full length
SDI-1 protein. The HA tag provided a unique antigen for
immunostaining, and permitted a determination of whether the
protein products were expressed and where they were localized
within the cell. To ensure that the HA tag did not interfere
20 with the DNA synthesis inhibitory activity of SDI-1, the cDNAs
encoding either the full length (164 amino acid) or the
truncated (amino acids 1-71) species were also fused to the HA
sequence at the carboxy terminus. The HA tag sequence was
introduced by the polymerase chain reaction (PCR) using the
25 primers:

SEQ ID NO:14 TCTAGGCCTGTACGGAAGTG

(splice site in pCMV vector)

SEQ ID NO:15 TAGGAATTCAGTCTAAGCGTAATCTGG

AACATCGTATGGGTAGGGCTTCCTCTTGGA

- 5 The inhibitory activity of these cDNAs was the same as that of constructs without the HA tag. Another control construct was deleted in amino acids 16-52 and had no inhibitory activity whether it was tagged or not. Interestingly, and in further support of the importance of the integrity of the amino
- 10 terminal region of the molecule in growth inhibition, cDNAs tagged with HA at the amino terminus had no growth inhibitory activity.

Deletions were then introduced into the protein-coding region of the SDI-1 cDNA in plasmid pCMVsdil(1-686)HA by PCR.

- 15 The tag allowed one to ascertain that the wild-type and mutated proteins were expressed in cells transfected with the various constructs and also to determine the localization of the mutant protein.

- 20 The following primer sets were used to introduce the indicated deletions (Table 14):

Table 14		
Amino Acids Deleted	Seq Id No	Nucleotide Sequence
24-29	16	TTCGGCCCTCGAGGCTGAGCCGCGACTGT

Each primer was used with a primer hybridizing within the vector to amplify a portion of the SDI-1 plasmid, the amplified materials from two reactions were pooled and permitted to anneal. Single-stranded regions were filled in with polymerase, and the fragments were then ligated together to produce the desired covalently closed circular vectors. The use of SEQ ID NO: 26-27 replaced SDI-1 amino acids 58-61 with the tripeptide "Ser-Arg-Ala." The truncated constructs thus encoded the amino terminal end of the protein up to amino acid 123, 82, 71, 52 and 16, respectively. All constructs were sequenced to verify that the desired deletions had been made, that the integrity of the HA tag was intact and to confirm that

no additional mutations had been introduced into the constructs.

5 HCA2 and MDAH 041 cells were co-transfected with pCMV β -gal and plasmids carrying the above-described SDI-1 mutated DNA using calcium phosphate precipitation. The MDAH 041 cell line was derived from a Li-Fraumeni syndrome patient, and does not synthesize p53 since a frame shift mutation causes premature termination in the amino terminal region of the p53 molecule. MDAH041 were the cells of choice for these 10 transfections because they do not express detectable levels of SDI1. They, therefore, provided a more sensitive assay for small changes in DNA synthesis inhibitory activity that might be expected in the case of these minimally deleted mutant constructs.

15 One μ Ci/ml tritiated thymidine was added to the culture medium 24 hours after transfection and the cells were incubated for an additional 36 hours. The cells were fixed, stained for β -galactosidase activity, and processed for autoradiography to determine the percentage of β - 20 galactosidase positive cells that had synthesized DNA. Percent inhibition was determined relative to control cells co-transfected with the pCMV vector and pCMVB-gal.

Deletion of amino acids 53-58 was found to result in the greatest loss of DNA synthesis inhibitory activity (which was 25 about 50% that of the full length cDNA). Two other deletions (of amino acids 42-47 and of amino acids 66-71 of SEQ ID NO:2) also caused a decrease in activity, although of lesser extent. Since the possibility existed that a particular construct that was actually minimally inhibitory might exhibit greater 30 inhibition if a larger amount of DNA were transfected, the amount of plasmid DNA was reduced to 200 ng per transfection. The results of transfection experiments using this lower amount of DNA confirmed that the deletion of amino acids 42-47 and 66-71 of SEQ ID NO:2 did indeed result in a loss of 35 inhibitory activity, and that the deletion of amino acids 53-58 of SEQ ID NO:2 resulted in a significant loss in ability to inhibit DNA synthesis. Deletions 24-29, 30-35 had activity similar to that of wild type at both DNA concentrations. These results

indicate that the critical region of the protein product of SDI1 must lie between amino acids 42 and 71. They therefore support the conclusion that peptides having the sequence of SEQ ID NO:242-71 and non-peptide molecules that mimic a reactive side group of SEQ ID NO:242-71 comprise mimetics of SDI-1. In particular, a preferred mimetic has the amino acid sequence SEQ ID NO:249-77. A particularly preferred peptide mimetic has a sequence: WNFDFXXXXPLEGXXXWXXVXXXXLPXXY (SEQ ID NO:34). Such a mimetic may be formed using the above-described methods and primers having the sequences:

SEQ ID NO:35 CAGAATCACAAGCCACTCGAGGGTAAG
 TACGAGTGGGAGCGTGTGCGGGGCCTT

SEQ ID NO:36 CTTACCCTCGAGTGGCTTGTGATT
 CTGAAAGTCGAAGTTCCATCGCTC

15 A preferred nonpeptide mimetic has residues that mimic reactive side groups of SEQ ID NO:34.

To determine whether the DNA synthesis inhibition caused by these mutants was occurring through inhibition of cdk kinases, the binding of *in vitro* translated deletion mutant proteins products with purified cdk2protein was examined. Thus, the various deletion mutants of SDI-1 were translated in reticulocyte lysates (Promega) using pBluescript based plasmids as transcription templates for the T7 RNA polymerase. For *in vitro* binding, 45 µl of the translation product was added to 500 µl binding buffer (50 mM Tris/HCl, pH 7.5, 120 mM NaCl, 2 mM EDTA, 0.1% NP-40, 1 mM NaF, 0.1 mM sodium vanadate, 5 µg/ml leupeptin, 5 µg/ml soybean trypsin inhibitor, 5 µg/ml aprotinin) containing 1ug cdk2 protein purified from a baculovirus expression system. The mixture was gently rocked for 1 hour at 4° C and then 7.5 µg anti-cdk2 rabbit polyclonal antibody was added. Mixing was continued for 1 hour at 4° C. The immunocomplex was absorbed by incubation with 40 µl protein G plus A beads for 2 hr. The matrices were then washed three times with 0.5 ml of binding buffer prior to electrophoresis and autoradiography.

All the mutant constructs produced protein which had a molecular weight of approximately 23 kD. To verify that the proteins were indeed deleted SDI-1 products, they were immunoprecipitated using CA5 (a monoclonal antibody against the HA tag sequence) and all successfully precipitated the antibody. The wild type protein SDI-1 and the three deletions, 24-29, 30-35, 72-77, bound cdk2 protein efficiently, suggesting that the DNA synthesis inhibitory activity of these constructs was the result of binding to cdk2. In contrast, the mutants, 42-47, 53-58, and 66-71, which had decreased inhibitory activity did not bind cdk2.

Immunohistochemistry

The intracellular localization of SDI-1 has been reported to be nuclear and there is a putative nuclear translocation signal at the 3' end of the coding region of the gene. However, as indicated above, a C-terminus-truncated protein (SDI-11-71), which lacks this putative nuclear translocation signal was found to have the same inhibitory activity as the wild type protein (Table 13). In order to determine the localization of the protein products of the various deletion mutant constructs of SDI-1 following their transfection into the MDAH 041 cells, immunostaining of the HA tag was conducted.

For immunostaining, cells were seeded onto glass coverslips at about 50% confluent density, and allowed to adhere overnight before transfection. Following transfection cells were incubated at 37° C for 24 hours, then washed twice with phosphate buffered saline (PBS) and fixed in freshly prepared formaldehyde solution [4% (wt/vol) paraformaldehyde in PBS] for 15 min at room temperature. The fixed cells were then washed in PBS and incubated in 50mM glycine in PBS at room temperature for 10 min. Cells were again washed with PBS and permeabilized by incubation in 0.2% Triton-X100 in PBS, at room temperature, for 10 min. After additional washings with PBS immunostaining was performed according to the direction of the ABC kit (source). The primary antibody (12CA5) was diluted 1:1000 in the buffer available in the kit.

The deleted, but still growth inhibitory proteins were found to localize to the nucleus whereas a high percentage of

cells expressing the inactive or less active mutant proteins exhibited cytoplasmic staining. These data, along with the cdk binding results, strongly indicate that translocation of SDI-1 into the nucleus is dependent on the formation of a SDI-1 cyclin-cdk complex.

Thus, truncation of the C terminal region of SDI-1 revealed that SDI-1 molecules having amino acids 1-71 of SEQ ID NO:2 exhibited almost the same capacity to inhibit DNA synthesis as the full length SDI-1 protein (SEQ ID NO:2). Fine deletion analysis showed that the amino acids in region 42-71 of SEQ ID NO:2 were crucial for both kinase inhibition and DNA synthesis inhibition. This result was also confirmed by results which showed that SDI-1 molecules having deletions of the amino acids in region 42-71 of SEQ ID NO:2 exhibited no binding activity.

From immunohistochemical analysis, most of the active mutant protein was found to be localized in the nucleus. In contrast, SDI-1 mutants that lacked activity were found to be localized in the cytoplasm, indicating that translocation of SDI-1 into the nucleus is mainly depend upon the ability of making the complexes with cdk-cyclins rather than upon the existence of nuclear translocation-like sequences on the C-terminus of the SDI-1 protein. Because of the significance of region 42-71 of SEQ ID NO:2 on kinase inhibition and DNA synthesis inhibition, this region was studied in great detail. This analysis clearly indicated that homology regions (49-53 and 58-61 of SEQ ID NO:2) provided a new inhibitory motif among cdk inhibitors (such as SDI-1 and p27).

The above results clearly implicate the amino terminal region of the SDI-1 protein as the area involved in inhibiting DNA synthesis. The fine mapping studies implicate the region between amino acids 48-65 as critical for the negative growth effects of the gene. The data also demonstrate that when the gene product is involved in active inhibition it localizes to the nucleus of the cell and that inactive forms of the protein remain in the cytoplasm. With respect to this latter observation, it is of interest to note that a putative nuclear localization signal exists in the carboxy terminal region of the

protein. Nonetheless, the deletion of amino acids 72-164 which eliminates this signal sequence, is fully capable of inhibiting DNA synthesis and is expressed in the nucleus. This indicates that some other molecule(s), perhaps the complexes of cyclins, cdks and PCNA with which SDI-1 associates, transports the SDI-1 protein the nucleus.

While the invention has been described in connection with specific embodiments thereof, it will be understood that it is capable of further modifications and this Application is intended to cover any variations, uses, or adaptations of the invention following, in general, the principles of the invention and including such departures from the present disclosure as come within known or customary practice within the art to which the invention pertains and as may be applied to the essential features hereinbefore set forth and as follows in the scope of the appended claims.

WHAT IS CLAIMED IS:

1. A purified nucleic acid molecule that encodes a protein or polypeptide capable of inhibiting DNA synthesis in a recipient cell.

2. The nucleic acid molecule of claim 1 wherein said protein or polypeptide is capable of associating with a cyclin or a cyclin-dependent kinase.

3. The nucleic acid molecule of claim 2, wherein said cyclin is cyclin D1, and said cyclin-dependent kinase is CDK2.

4. The nucleic acid molecule of claim 3, wherein said molecule encodes SDI-1, an SDI-1 fusion protein or a fragment of SDI-1.

5. The nucleic acid molecule of claim 3, wherein said molecule encodes an analog of SDI-1.

6. The nucleic acid molecule of claim 3 wherein the expression of said protein or polypeptide is regulated by a tumor suppressor gene.

7. The nucleic acid molecule of claim 6, wherein said molecule encodes SDI-1, an SDI-1 fusion protein or a fragment of SDI-1.

8. The nucleic acid molecule of claim 6, wherein said molecule encodes an SDI-1 fusion protein.

9. The nucleic acid molecule of claim 8, wherein said SDI-1 fusion protein comprises SEQ ID NO:10.

10. The nucleic acid molecule of claim 3, wherein said molecule is capable of hybridizing to the complement of the nucleic acid sequence of SEQ ID NO:1.

11. An oligonucleotide having a length of at least 19 nucleotides, wherein said oligonucleotide is capable of hybridizing to the complement of the nucleic acid sequence of SEQ ID NO:1.

5

12. The oligonucleotide of claim 11, wherein said oligonucleotide has a nucleotide sequence of an oligonucleotide fragment of SEQ ID NO:1.

10

13. The oligonucleotide of claim 11, wherein said oligonucleotide has a length of at least 25 nucleotides.

14. The oligonucleotide of claim 12, wherein said oligonucleotide has a length of at least 25 nucleotides.

15

15. An oligonucleotide having a length of at least 19 nucleotides that is capable of hybridizing to SEQ ID NO:1.

20

16. The oligonucleotide of claim 15, wherein said oligonucleotide has a length of at least 25 nucleotides.

17. An oligonucleotide having a length of at least 19 nucleotides that is completely complementary to a fragment of SEQ ID NO:1.

25

18. The oligonucleotide of claim 17, wherein said oligonucleotide has a length of at least 25 nucleotides.

19. An oligonucleotide capable of inhibiting the expression of SDI-1 by formation of a triplex structure, wherein said oligonucleotide consists of only G and C residues, and is at least 20 nucleotides in length, and has a nucleotide sequence
5 that can hybridize with a double-stranded nucleic acid molecule that encodes SDI-1, said hybridization being to a region of said double-stranded molecule that is at least about 65% purine or at least about 65% pyrimidine, wherein said oligonucleotide has a G residue when a complementary location
10 in the SDI-1-encoding nucleic acid molecule is a GC base pair and a T residue when a complementary location in the SDI-1-encoding nucleic acid molecule is an AT base pair.

20. An purified antagonist of a protein or polypeptide
15 capable of:
(i) inhibiting DNA synthesis in a recipient cell and
(ii) associating with a cyclin or a cyclin-dependent kinase.

21. The antagonist of claim 20, wherein said antagonist is
20 a nucleic acid molecule.

22. The antagonist of claim 21, wherein said cyclin is cyclin D1, and said cyclin-dependent kinase is CDK2.

23. The antagonist of claim 22, wherein said nucleic acid
25 molecule is complementary to a nucleic acid molecule that encodes SDI-1.

24. The antagonist of claim 20, wherein said antagonist is
30 a protein.

25. The antagonist of claim 24, wherein said protein is an antibody.

26. An antibody capable of binding SDI-1.
35

27. The antibody of claim 26, wherein said antibody is a monoclonal antibody.

28. The antibody of claim 26, wherein said antibody is a polyclonal antibody.

5 29. A purified protein or polypeptide capable of:
 (i) inhibiting DNA synthesis in a recipient cell and
 (ii) associating with a cyclin or a cyclin-dependent
 kinase.

10 30. The protein of claim 29, wherein said cyclin is cyclin
 D1, and said cyclin-dependent kinase is CDK2.

 31. The protein of claim 29, wherein said protein is
 encoded by a nucleic acid molecule, and wherein said nucleic
15 acid molecule or its complement is capable of hybridizing to
 the nucleic acid sequence shown in Figure 5 <SEQ ID 1>.

 32. The protein of claim 29, wherein said protein is SDI-1.

20 33. The protein of claim 29, wherein said protein is
 induced by the product of a tumor suppressor gene.

 34. An analog of the protein of claim 28, wherein said
 analog is capable of inhibiting DNA synthesis in a recipient cell
25 and associating with a cyclin or a cyclin-dependent kinase.

 35. The analog of claim 34, wherein said analog is a
 protein.

30 36. The analog of claim 35, wherein said protein is a
 mutant SDI-1 protein.

 37. A method for inhibiting the proliferation of a cell,
 comprising introducing into said cell a drug which comprises an
35 SDI-1 molecule that (i) inhibits DNA synthesis in a recipient
 cell and (ii) associates with a cyclin or a cyclin-dependent
 kinase.

38. The method of claim 37, wherein said SDI-1 molecule comprises a protein or protein fragment.

5 39. The method of claim 38, wherein said method additionally comprises providing a chemotherapeutic agent, an antiviral agent, or an antimicrobial agent.

10 40. The method of claim 37, wherein said SDI-1 molecule comprises a nucleic acid molecule.

41. The method of claim 40, wherein said nucleic acid molecule encodes SDI-1, or a fragment of SDI-1.

15 42. The method of claim 37, wherein said cell is a human cell.

20 43. A method of determining the presence or concentration of SDI1 in a sample which comprises contacting said sample with an antibody capable of binding SDI-1, and determining the presence or amount of any SDI-1 protein bound to said antibody.

25 44. A method for inhibiting DNA synthesis in a human cell which comprises providing to said cell an effective amount of a nucleic acid molecule that encodes a protein capable of inhibiting DNA synthesis in a recipient cell.

30 45. The method of claim 44, wherein said provided nucleic acid molecule is expressed in said cell, and wherein said expression produces a protein capable of impairing the activity of a cyclin or a cyclin-dependent kinase.

46. The method of claim 45, wherein said cyclin is cyclin D1, and said cyclin-dependent kinase is CDK2.

35 47. The method of claim 46, wherein said nucleic acid molecule or its complement is capable of hybridizing to the nucleic acid sequence shown in Figure 5 <SEQ ID 1>.

48. The method of claim 43, wherein said nucleic acid molecule encodes a protein analog of a protein encoded by a sequence present in the nucleic acid sequence shown in Figure 5 <SEQ ID 1>, wherein said analog is capable of impairing the activity of a cyclin or a cyclin-dependent kinase.

49. The method of claim 43, wherein said cyclin is cyclin D1, and said cyclin-dependent kinase is CDK2.

50. The method of claim 43, wherein said cell is a tumor cell.

51. The method of claim 43, wherein said cell is a cell in in vitro culture.

52. A method for repressing an inhibition of DNA synthesis in a quiescent or senescent human cell which comprises providing to said cell an effective amount of a nucleic acid molecule having a sequence complementary to an RNA molecule that encodes a protein capable of inhibiting DNA synthesis in a recipient cell, and having a length sufficient to permit said nucleic acid molecule and said RNA molecule to hybridize to one another under physiological conditions.

53. The method of claim 52, wherein said cell is a skin cell.

54. The method of claim 52, wherein said cell is an endothelial cell.

55. The method of claim 52, wherein said cell is present in wound or burn tissue.

56. The method of claim 52, wherein the repression of the inhibition of DNA synthesis of said cell permits angiogenesis to occur.

57. The method of claim 52, wherein said cell is removed from a patient, and said nucleic acid molecule is provided to said cell ex vivo, and wherein said recipient cell is subsequently introduced back into said patient.

5

58. The method of claim 52, wherein said cell is removed from a patient, and said nucleic acid molecule is provided to said cell ex vivo, and wherein said recipient cell is subsequently cultured ex vivo to form progeny cells that are introduced into said patient.

10

59. The method of claim 52, wherein said cell is a normal cell, and wherein the provision of said nucleic acid molecule is sufficient to convert said normal cell into an immortalized cell, capable of forming an immortalized cell line in vitro.

15

60. The method of claim 59, wherein said immortalized cell line is used to produce a desired biological compound.

20 61. A method for directing the delivery of a pharmacological agent into a target cell which comprises:

(A) conjugating said pharmacological agent to an SDI moiety, said moiety selected from the group consisting of SDI-1 and a fragment of SDI-1 capable of being transported into said target cell; and

25

(B) incubating said conjugated molecule in the presence of said target cell under conditions sufficient to permit said SDI moiety to be transported into said target cell; said transport accomplishing the delivery of said agent into said target cell.

FIGURE 6

INTERNATIONAL SEARCH REPORT

 International application No.
PCT/US94/09700

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : Please See Extra Sheet.

US CL : Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/85.8, 88; 435/4, 7.1; 530/350, 387.1, 388.1, 388.15, 395, 416, 417; 514/2, 8, 12; 536/23.1, 23.4, 23.5.

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

 Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
APS, CAS ONLINE, BIOSIS, MEDLINE.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y,P	CELL, VOLUME 75, ISSUED 19 NOVEMBER 1993, W. S. EL-DEIRY ET AL., "WAF1, A POTENTIAL MEDIATOR OF P53 TUMOR SUPPRESSION", PAGES 817-825, FIGURES 1-6.	1-43
Y,P	CELL, VOLUME 75, ISSUED 19 NOVEMBER 1993, J W HARPER ET AL., "THE P21 CDK-INTERACTING PROTEIN CIP1 IS A POTENT INHIBITOR OF G1 CYCLIN-DEPENDENT KINASES", PAGES 805-816, FIGURES 1-6.	1-43
Y,P	EXPERIMENTAL CELL RESEARCH, VOLUME 211, ISSUED MARCH 1994, A. NODA ET AL., "CLONING OF SENESCENT CELL-DERIVED INHIBITORS OF DNA SYNTHESIS USING AN EXPRESSION SCREEN", PAGES 90-98, FIGURES 1-8.	1-43

☒ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	T	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	X	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	Y	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	A	document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means		
"P" document published prior to the international filing date but later than the priority date claimed

C (Continuation). DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y,P	NATURE, VOLUME 366, ISSUED 16 DECEMBER 1993, Y. XIONG ET AL., "P21 IS A UNIVERSAL INHIBITOR OF CYCLIN KINASES", PAGES 701-704, FIGURES 1-4.	1-43

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US94/09700

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-43

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US94/09700

A. CLASSIFICATION OF SUBJECT MATTER:

IPC (6):

A23J 1/00; A61K 31/70, 35/14, 37/00, 39/00; A01N 37/18, 43/04; C07H 17/00; C07K 1/00, 14/00, 2/00, 17/00; C12Q 1/00; G01N 33/53.

A. CLASSIFICATION OF SUBJECT MATTER:

US CL :

424/85.8, 88; 435/4, 7.1; 530/350, 387.1, 388.1, 388.15, 395, 416, 417; 514/2, 8, 12; 536/23.1, 23.4, 23.5.

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

- I. CLAIMS 1-43 ARE, DRAWN TO NUCLEIC ACID ENCODES SDI-1, SDI-1 ANTAGONIST, ITS ANTIBODY AND A METHOD OF DETERMINING SDI-1.
- II. CLAIMS 44-51 ARE, DRAWN TO A METHOD FOR INHIBITING DNA SYNTHESIS IN A HUMAN CELL.
- III. CLAIMS 52-60 ARE, DRAWN TO A METHOD FOR REPRESSING AN INHIBITION OF DNA SYNTHESIS IN A HUMAN CELL.
- IV. CLAIM 61 IS, DRAWN TO A METHOD FOR DIRECTING THE DELIVERY OF A PHARMACOLOGICAL AGENT INTO A TARGET CELL.

THE PRODUCTS/PROCESS OF GROUPS I-IV ARE SEPARATE AND DISTINCT INVENTIONS IN THAT EACH IS DEFINED BY A DIFFERENT NUCLEOTIDE SEQUENCE AND DIFFERENT EXPRESSION PROPERTIES AND FUNCTIONS ALL OF WHICH CONSTITUTE THE SPECIAL TECHNICAL FEATURES WHICH DEFINE THE CONTRIBUTION OF EACH INVENTION. SINCE THESE SPECIAL TECHNICAL FEATURES ARE NOT SHARED BY EACH PRODUCT AND SINCE THE COMMON FEATURES DO NOT ESTABLISH AN ADVANCE OVER THE PRIOR ART, THE INVENTIONS OF GROUPS I-IV DO NOT SHARE A TECHNICAL RELATIONSHIP AND DO NOT FORM A SINGLE INVENTIVE CONCEPT WITHIN THE MEANING OF RULE 13.2.
